# The TIMBER RESOURCES of MAINE

**By Roland H. Ferguson and Neal P. Kingsley**

U.S.D.A. FOREST SERVICE RESOURCE BULLETIN NE-26
1972

NORTHEASTERN FOREST EXPERIMENT STATION, UPPER DARBY, PA.
U.S. FOREST SERVICE, U.S. DEPARTMENT OF AGRICULTURE
WARREN T. DOOLITTLE, DIRECTOR

## FOREWORD

UNDER the authority of the McSweeney-McNary Forest Research Act of May 22, 1928, and subsequent amendments, the Forest Service, U. S. Department of Agriculture, conducts a series of continuing forest surveys of all states to provide up-to-date information about the forest resources of the Nation.

The first forest survey of Maine was made in 1954-58 by the Northeastern Forest Experiment Station, with cooperation from many individuals, forest industries, and state agencies.

A resurvey of the timber resources of Maine was made in 1968-70, again with the cooperation of many persons and agencies. The Maine State Legislature, the forest industries, and the United States Department of Commerce contributed funds for aerial photography and purchase of the aerial photographs that were used for the resurvey. The Maine Forestry Department provided air transport to otherwise inaccessible areas, quarters for the Forest Survey crews, financial assistance, aerial photographs and information on forest-land ownership and output of timber products. The State of Maine Bureau of Taxation, Seven Islands Land Company, Great Northern Paper Company, Scott Paper Company, and Diamond International Corporation lent aerial photographs for field-plot locations. The forest industries that provided assistance and quarters for field crews were Great Northern Paper Company, International Paper Company, and Oxford Paper Comapny. The Seven Islands Land Company also provided assistance and quarters for the field crews. The entire operation received excellent help and cooperation.

The resurvey of the State was directed by Carl E. Mayer, leader of the Forest Survey project. He was assisted by John R. Peters, who supervised many field crews over the 3-year period. Joseph E. Barnard was responsible for applying the general sampling procedures used by the Forest Survey to meet the specific requirements for the Maine inventory. This involved considerations of sampling accuracy desired, sampling procedures to be used, and final data requirements. He and David R. Dickson augmented the generalized computer system FINSYS for the specific data requirements of the Maine inventory. This included the processing of nearly 100,000 records of plot and tree data on a large high-speed computer system. The authors and Barnard checked the consistency of the new inventory with the previous inventory. They made frequent use of the TRAS model in this phase of the data analysis.

James T. Bones, with the cooperation of the Maine Forestry Department, collected and compiled data on timber-products output and plant residues. Teresa M. Bowers assisted in computing information pertinent to the sampling design and compiling the data tables included in this report. Carmela M. Hyland assisted with administrative services for the field crews and typed the manuscript and tables of this report.

The last field plot in Maine was taken in December 1970; photo interpretation was completed in April 1971; and the final computer output of the resource data was available in May 1971.

# The TIMBER RESOURCES of MAINE

## THE AUTHORS

ROLAND H. FERGUSON, research forester, received his bachelor of science degree in forestry at Oregon State College in 1931, and joined the USDA Forest Service in 1934. After working in the southern pine and Douglas-fir regions, he came to the Northeastern Forest Experiment Station in 1945. He has participated in various aspects of the Forest Survey, and since 1957 he has been a resource analyst in the Forest Survey unit.

NEAL P. KINGSLEY, research forester, received his bachelor's degree in forestry from the University of New Hampshire in 1961 and his master's degree in forest economics from the same university in 1963. He joined the Northeastern Forest Experiment Station in August 1962 where he is resource analyst in the Experiment Station's Forest Survey unit.

MANUSCRIPT RECEIVED FOR PUBLICATION 21 OCT. 1971

## COVER PHOTO

GREAT NORTHERN PAPER COMPANY

A towboat pulls a "bag boom" of pulpwood through Chesuncook Lake in the shadow of Mt. Katahdin. This scene will soon be a thing of the past. Because of a concern for water quality and possible damage to the environment, the 105th Maine Legislature has mandated that all pulpwood and long-log drives on principal rivers must cease by 1976. Booming through the lakes has been common practice in river driving.

## CONTENTS

# The Resurvey

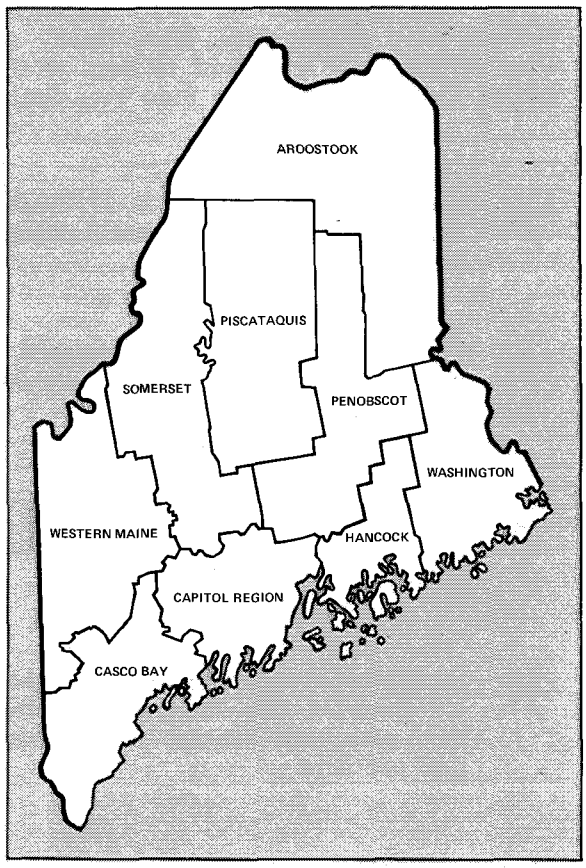
THE FIRST forest survey of the timber resources in Maine was conducted from 1954 to 1958. Now the second forest survey of the State, some 12 years later, shows that a number of important changes have taken place.

This report summarizes the present timber-resource situation and the changes that have taken place since the initial survey. Trends in timber supply, including a discussion of timber availability, are pointed out, and projections of future timber supply are made.

## NINE GEOGRAPHIC UNITS

To obtain meaningful data on other than state totals, the State was divided into nine geographic sampling units for the resurvey. These units consist of one to four counties. Each unit was delineated to be as homogenous as possible. All but one of the sampling units contain more than 1 million acres of commercial forest land.

In the initial forest survey, six sampling units of irregular boundaries were recognized. It is planned to use the nine units defined for this re-inventory as the basic units for the next resurvey, thus permitting comparisons of trends at less than the statewide level. Because of the changes in the sampling units, it is not possible to compare unit or county estimates of timber volumes in this report with those published in the timber resource report for 1959. Comparisons of volume estimates given in this report were made only after putting the initial survey estimates on the same basis as the resurvey. The improved accuracy of the new estimates far outweighs the lack of directly comparable unit data for both inventories.



The geographic sampling units in Maine, 1968-70.

## SAMPLING THE RESOURCE

In the resurvey a large number of initial field plots were remeasured to provide estimates of average annual net timber growth, average annual timber removals, land-use change, and to update the initial forest-inventory volume estimates. To develop an independent second estimate, new field plots were established and measured. These two samples yielded independent estimates, which were weighted and combined to give the current estimates of forest area and timber volume reported in this publication. A more detailed discussion of the design and sampling procedure can be found in the appendix.

Sampling errors, which indicate the reliability of the estimates, are shown for most of the totals and subtotals of the new estimates. Definitions of forest-survey terms and the discussion about reliability of the estimates are presented in the appendix. Users of these timber-resource data are strongly advised to read these definitions and explanations carefully.

# Highlights of the Findings

In the 12 years between the initial forest survey and the resurvey, many significant changes have taken place. Here briefly are some of the more important findings of this second forest survey of the Pine Tree State:

- Total forest land area is 17,749,000 acres, an increase of almost 3 percent since 1959.
- Commercial forest land increased 3 percent and now totals 16,900,000 acres.
- Forest industries own 49 percent of the commercial forest land, up from 38 percent in 1959.
- Sawtimber stands make up more than one-third of the commercial forest land area and average 3,830 board feet per acre.
- Growing-stock volume increased 23 percent to 21 billion cubic feet. Softwoods increased at a much greater rate than hardwoods.
- Softwoods make up 70 percent of the growing-stock volume. Spruces account for 26 percent, balsam fir 24 percent, and white pine 7 percent.
- Poletimber trees make up 57 percent (12 billion cubic feet) of the total growing-stock volume.
- Sawtimber volume increased 19 percent to 35 billion board feet. Largest increases were in spruce and fir volumes.
- About two-thirds of the sawtimber volume is in trees less than 15.0 inches d.b.h.
- Annual net growth for 1970 was 711 million cubic feet of growing stock, including 1,622 million board feet of sawtimber.
- Timber removals for 1970 were 409 million cubic feet of growing stock, including 1,299 million board feet of sawtimber.
- Although growth exceeds removals for total growing stock, the growth-to-removals ratios of some important species and sizes of timber show overcutting.
- More white pine, northern white-cedar, yellow birch, and sugar maple sawtimber volume is being cut than grown.
- Projections of future timber supply show that, if present removal trends continue, hardwood removals will exceed growth within a few years, and softwood removals will exceed growth before the turn of the century.
- A greatly increased effort at forest management, particularly of hardwoods, is indicated if timber growth in Maine is to keep pace with demand.

# Timber-Resource Trends

Nine-tenths of Maine's land area is covered by forests, and less than 5 percent of the forest area is classified as noncommercial. No other state has so large a proportion of its land area in forests. Maine's forests supply the timber industries with huge volumes of wood; Maine's forests protect the water supply of hundreds of lakes, ponds, and streams; Maine's forests provide recreation in many forms, such as canoeing, fishing, and hunting.

Since the first forest survey of Maine, many definitions, procedures, and methods have been changed as a result of improved forest-inventory and data-processing techniques. This means that to analyze actual trends between surveys, the initial survey estimates must be put on a basis comparable to the resurvey estimates. The 1959 estimates are valid for the procedures and definitions used at that time, and should not therefore be discounted *(2)*. The trends in commercial forest-land area, growing-stock volume, and sawtimber volume, after adjustment of the 1959 data to the resurvey standards, are presented below.

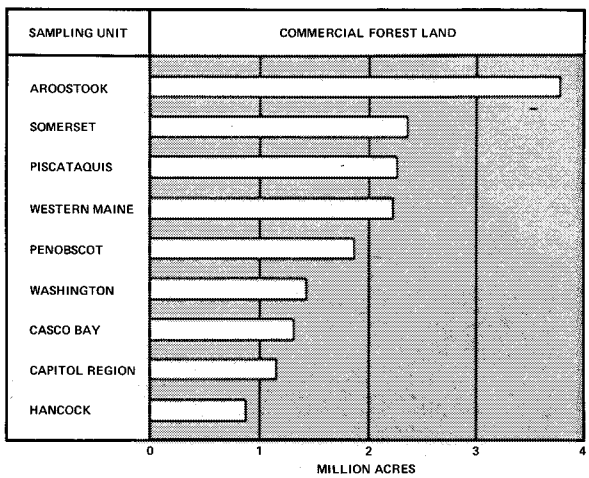
*Change in area and volume, 1959-71*

| | *1959* | *1971* | *Change* |
|---|---|---|---|
| Commercial forest land: *(thousand acres)* | 16,417 | 16,894 | + 477 |
| Growing-stock volume: *(million cubic feet)* | | | |
| Softwoods | 11,460 | 14,763 | +3,303 |
| Hardwoods | 5,769 | 6,490 | + 721 |
| Total | 17,229 | 21,253 | +4,024 |
| Sawtimber volume: *(million board feet)* | | | |
| Softwoods | 18,832 | 23,456 | +4,624 |
| Hardwoods | 10,255 | 11,064 | + 809 |
| Total | 29,087 | 34,520 | +5,433 |

## SMALL CHANGES IN TOTAL FOREST AREA

Land-use changes between surveys resulted in a net increase in forest-land area of 2.6 percent. Maine is still the most heavily forested state in the Nation: 90 percent of its land area is classed as forest land. About 60 percent of the commercial forest land is in the four northern counties—Aroostook, Penobscot, Piscataquis, and Somerset. Aroostook County, with 3,800,000 acres of commercial forest land, has 22 percent of the State's total. The commercial forest-land area in the small counties that make up the Casco Bay and Capitol Region units average about 300,000 acres.

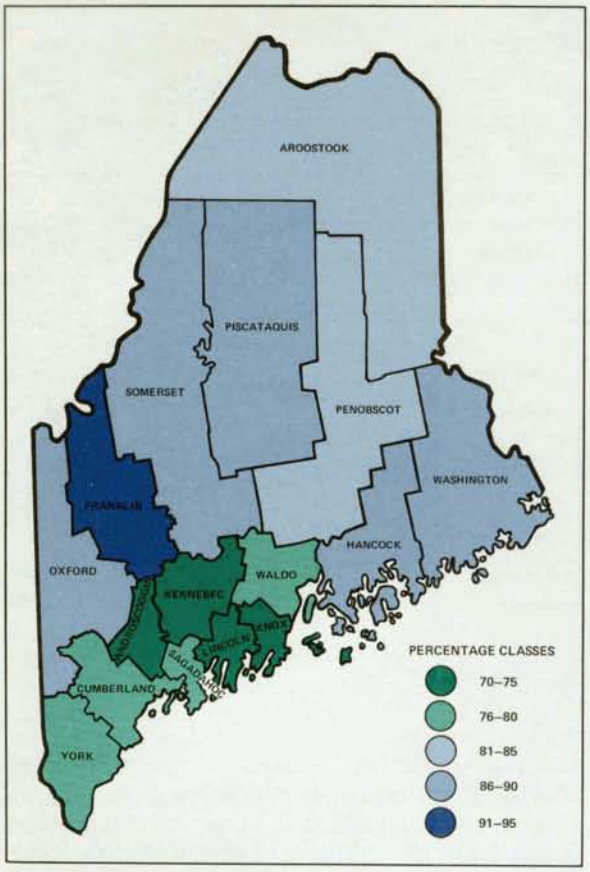
The commercial forest-land area in Maine, by geographic units.



The commercial forest-land area in the State increased 2.9 percent, to 16.9 million acres. All but one county—Somerset—had increases in commercial forest land. Commercial forest land makes up 86 percent of the land area in the State. The percentage for individual counties ranges from 70 percent (Kennebec and Knox Counties) to 91 percent (Franklin County).

Noncommercial forest land totals 854,000 acres and accounts for 4 percent of the total forest area. This acreage consists of 221,000 acres of productive-reserved forest land (174,000 acres in Baxter State Park, Piscataquis County) and 634,000 acres of nonproductive forest land. Three of the geographic units—Aroostook County, Penobscot County, and Western Maine—have more than 100,000 acres each of nonproductive forest land.

Percentage of land area in forest, by counties.



## OWNERSHIP HAS SEVERAL UNIQUE CHARACTERISTICS

### Forest Industries Own Nearly Half the Forest Land

Forest industries own 8.3 million acres—49 percent — of Maine's commercial forest land. Pulp and paper companies own about 93 percent of this land, lumber companies own about 7 percent, and various other wood-using firms own less than 1 percent. In no other state do forest industries own such a large share of the commercial forest land.

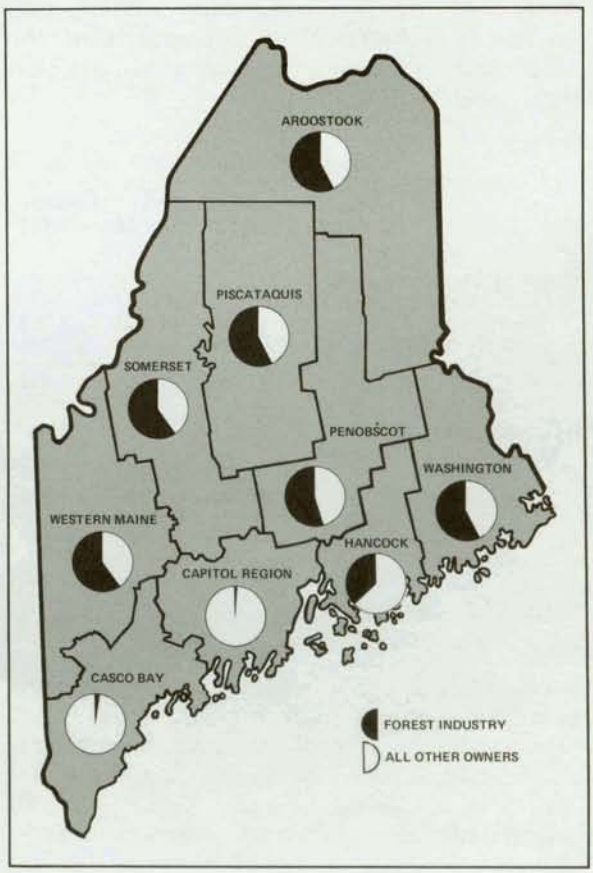
Most of the forest-industry holdings are in the large northern counties. Only in the three coastal geographic units—Casco Bay, Capitol Region, and Hancock County, do forest industries own less than 50 percent of the commercial forest land. In these three units—a total of nine counties—forest industries own only 10 percent of the commercial forest land.

Forest-industry holdings have increased about 27 percent since 1959—from 6.5 to 8.3 million acres. Most of this increase is the result of land acquisitions by several large forest-based companies. Although forest industries have increased their ownership since 1959—to insure continuous supply of raw material — most industry-owned land continues to be open to the general public for recreation.

Farmers own 1.1 million acres of Maine's commercial forest land, about 7 percent of the total. This total is down from the 1959 estimate of 2.0 million acres. The area held by all other private owners also declined—from 7.7 million acres in 1959 to 7.2 million acres in 1971—a drop of 6 percent.

Publicly owned commercial forest land in Maine totals only 311 thousand acres or about 2 percent of the total. Federal ownerships total less than 0.5 percent of the total.

Percentage of forest land owned by forest industry, by units.



State, and county and municipal ownerships account for about 1 percent each. Public ownership of commercial forest land in Maine is the lowest percentage of any forested state in the Nation.

### A Unique System of Forest Land Ownership

A substantial area of forest land in the "unorganized" northern portion of the State is held by owners who have a "common and undivided interest" in the land. This means that, for example, five owners may each own one-fifth of a parcel of land, yet no boundaries have been laid out and none of the owners can identify his portion on the ground. What's more, few of these owners have any need or desire to identify his portion. As far as is known, this system of land ownership is found nowhere else in the world.

The evolution of this system is an outgrowth of the early history of Maine. Most of what is now the State of Maine was first held by the Massachusetts Bay Company, later by the Province of Massachusetts, and then after the American Revolution by the Commonwealth of Massachusetts. In 1820 Maine, as one-half of the Missouri Compromise, separated from Massachusetts and became the twenty-third state to join the Union.

In the early years of statehood some 8 million acres of unlocated lands were jointly owned by both Massachusetts and the fledgling State of Maine. Both states were hard pressed for revenues and began selling these lands to investors and speculators. Because the owning of timberlands in such a remote region as northern Maine was considered a risky investment, many of these investors and speculators sought a means of spreading the risk.

To do this, as many as six individuals would purchase an unorganized township and hold it in common ownership and undivided

A township line in the unorganized portion of Maine can be distinguished only by the size of the timber. The township at the left was cut over 40 years ago; the one on the right was not.

GREAT NORTHERN PAPER COMPANY PHOTO

interest. With this form of ownership, no division lines were drawn, and each of the owners held his personal undivided share of the total. Gains and losses from the ownership of the land were also shared according to each owner's interest in the total. Thus, if some of the timber on the township were harvested, each owner would receive his proportionate share of the proceeds even if all the timber was harvested from one part of the township. Conversely, if a fire, insect outbreak, or other natural catastrophe struck the township, each owner would share in the loss according to his proportional share.

Surprisingly, this system has worked exceedingly well, and the cooperation between many diverse owners has generally been excellent. In fact, the system has succeeded so well that today a substantial portion of the land in the unorganized territory is still held in common and undivided ownerships, and the present owners show little inclination to alter the situation.

Over the years, inheritance and land sales have brought about more and more complex fractional shares. For instance, one 1963 deed conveyed a "31/52 part of a one-eighth interest in common and undivided" land in a certain township. A present-day owner has a 332/33280 common and undivided interest in this same township *(1)*.

### A Unique System of Forest Land Management

A unique system of managing forest land has developed in Maine as an outgrowth of the system of common and undivided ownership. Beginning as far back as 1840, groups of owners have banded together to form a unified land-management system. To do this, groups of owners have formed organizations, retained individuals or firms, or have delegated to one of the owners all management and ownership responsibilities. Under this system the manager essentially assumes the owner's role in forest management and other decisions regarding the land. The time, place, and volume of timber to be harvested is determined by the land manager. The proceeds from the sale, less operating costs, are then divided among the owners in accordance with each owner's share. This system makes it possible to manage these common and undivided ownerships as though they were a single ownership.

Not all the land in some townships that is held in common and undivided ownership belongs to owners who have joined together in a management organization. A common occurrence is for one of the major owners to be a large industrial firm. In such cases the land-management organization negotiates with the nonmember owner or owners and they jointly arrive at an agreement on management objectives and responsibilities.

At present there are approximately 3.2 million acres of commercial forest land in Maine that is being managed by such land-management organizations. This acreage is included in the individual private total in table 2 (appendix), because the actual owners of the land are in fact individuals. These lands are not considered forest-industry lands because neither the owners nor the land-management organizations operate wood-processing plants. All revenues derived from these lands are from the sale of standing timber, recreation leases, or in a few cases mineral leases.

These land-management organizations provide an opportunity for long-term forest management with continuity. Through successive generations of owners, management of the forest resources can proceed in planned and orderly fashion. The frequent change of owners is often a serious deterrent to successful forest management on individual private ownerships. Some of these lands have been managed for over 100 years.

## SIXTY PERCENT OF FOREST STANDS ARE FULLY STOCKED

Most of the forest land in Maine is well stocked. Much of it is probably overstocked for optimum growing conditions. Less than 1 percent of the commercial forest land is nonstocked. When all live trees, including rough and rotten trees, are considered in determining the stocking percentage, about nine-tenths of the commercial forest area is fully stocked. If rough and rotten trees are excluded from the determination, about six-tenths of the area is fully stocked. This situation is not unfavorable as far as the pulpwood industry is concerned, for much of the volume in rough trees is suitable for pulpwood. However, since such volume is not suitable for lumber, the situation for the lumber industry is much less favorable.

Forest stands that are medium to fully stocked with growing-stock trees occupy 90 percent of the commercial forest-land area. Of the total forest land owned by forest industry, 92 percent is in this category. All other ownerships have an average of 87 percent.

Nonstocked forest land in 1959 made up 3 percent of the total commercial forest land. In 1971 less than 1 percent (143,000 acres) of the total commercial forest land was classified as nonstocked.

### SAWTIMBER STANDS COVER MORE THAN ONE-THIRD OF AREA

Acreages in the stand-size categories for 1959 and 1971 are not on the same basis, so differences are not actual trends.

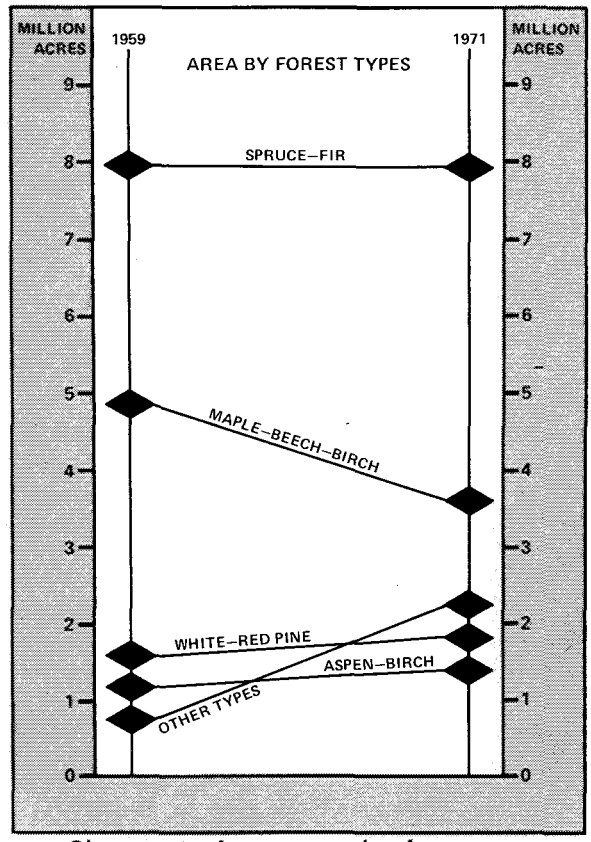
Sawtimber stands total 6,143,000 acres and average 3,800 board feet per acre. They make up 36 percent of the commercial forest area. About 45 percent of the commercial forest area (3,684,000 acres) owned by forest industry is classified as sawtimber stands. About 28 percent of the commercial forest land in all other ownerships is in sawtimber stands.

Acreage in poletimber stands adds up to 5,340,000 acres and accounts for 32 percent of the commercial forest area. These stands contain on the average 1,500 cubic feet (about 18 cords) per acre. Nearly 35 percent of the commercial forest land owned by forest industry is in this class, and 28 percent of the area in all other ownerships is in poletimber stands.

Area in sapling-seedling stands for all ownerships totals 5,269,000 acres and makes up 31 percent of the commercial forest-land area. About 20 percent of the forest industry's timber stands is in this class, and more than 40 percent of all other ownerships is in this class. Only 1 percent of the commercial forest-land area is nonstocked.

### MAPLE—BEECH—BIRCH TYPE DECREASED

Forest-type classifications used on the initial survey are fairly comparable to the forest-type classifications used on the resurvey. Differences in acreages between surveys can be attributed to actual trends.



Changes in forest area by forest types, 1959-71.

In the resurvey 20 local forest types were recognized. These local forest types were combined into seven national major types. (See table 40.) For example, the white pine-red pine-hemlock major type totals 1,812,000 acres. The total area of the three local forest types other than white pine accounts for more than one-half of the acreage—the hemlock type, 601,000 acres; the white pine-hemlock type, 299,000 acres; and the jack pine type, 26,000 acres.

*Maple-beech-birch.* — The maple-beech-birch forest type (northern hardwoods) was the only major type that decreased in area. In the timber stands that made up this type on the initial survey, the more valuable sugar maple and yellow birch were cut and most of the red (soft) maple was not. The proportion of red maple in many stands changed enough to make up a plurality of stocking. Therefore the forest-type classifications often changed to the elm-ash-red maple or other types.

The maple-beech-birch forest type de-

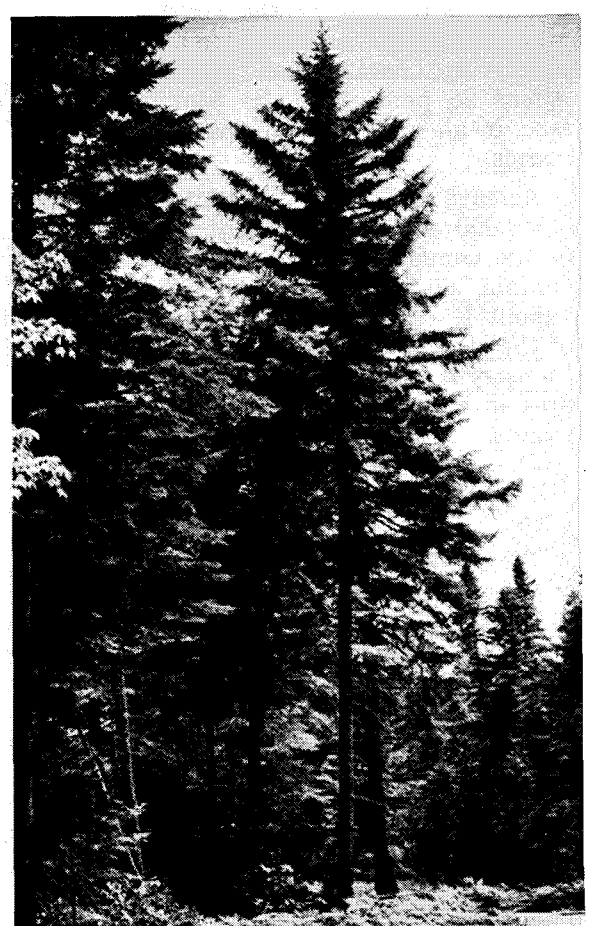
The maple-beech-birch type is the only major forest type in Maine that decreased in area.

creased more than 25 percent from 4,904,000 acres to 3,561,000 acres, but is still the second largest forest type and accounts for 21 percent of the total forest area in the State. This type makes up more than 18 percent of the commercial forest land in all countries except those in the four coastal units, where it averages about 8 percent. Somerset, Franklin, and Oxford Counties (with 26 percent of the State's commercial forest-land area) have 32 percent of the acreage in the maple-beech-birch forest type.

*Spruce-fir.*—This forest type covers 47 percent of the forest-land area in Maine. The 7,949,000 acres of commercial forest land in this type is more than double that for the next most extensive forest type (maple-beech-birch). This acreage is about the same as it was in 1959. Seventy percent of the spruce-fir type is found in the four northern counties — Aroostook, Penobscot, Piscataquis, and Somerset.

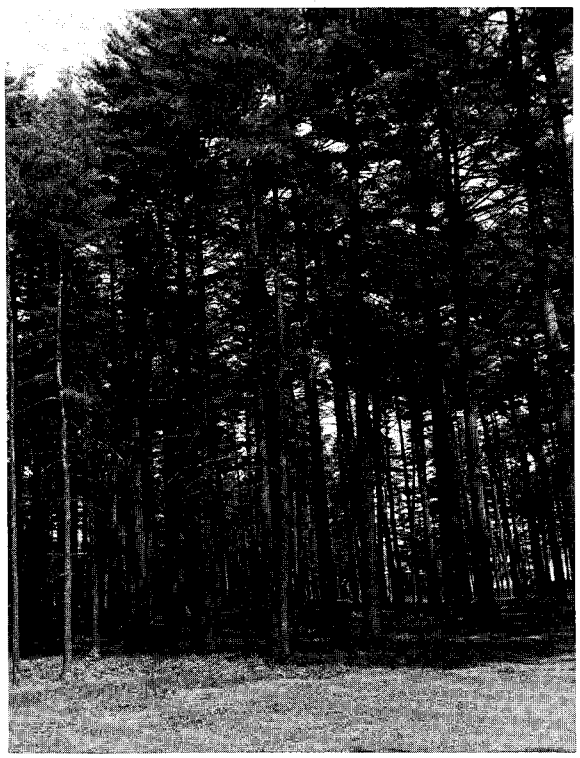
*White pine-red pine-hemlock.*—The white pine-red pine-hemlock forest type is the third most prevalent type; it accounts for a little more than 10 percent of the commercial forest land area. This major type increased 15 percent, from 1,577,000 acres to 1,812,000 acres; but the increase was in the local hemlock forest type. White pine was cut rather heavily during the period between surveys while hemlock was cut lightly. The local white pine types decreased about 2 percent in area, and the local hemlock type increased about 45 percent. The three largest counties — Aroostook, Piscataquis, and Somerset—have the least area in the white pine-red pine-hemlock forest type, less than 90,000 acres each.

*Elm-ash-red maple.*—This forest type increased in area from 484,000 acres to 1,714,000 acres and makes up 5 percent or more of the commercial forest land in all geographic units. This increase coincides with



The spruce-fir type is Maine's most extensive forest type.

White pine stands like this are hard to find in Maine.



MAINE FORESTRY DEPARTMENT PHOTO

the large increase in the volume of red maple and elm. The large increase in acreage of the elm-ash-red maple type almost offsets the large decrease in acreage of the maple-beech-birch type.

*Other forest types.*—The other major forest types together—oak and oak-pine and aspen-birch — increased 27 percent in area from 1,466,000 acres to 1,857,000 acres. The 438,000 acres of the oak types and 1,419,000 acres of the aspen-birch type account for 11 percent of the commercial forest-land area.

## INCREASE IN VOLUME WAS NOT EVENLY DISTRIBUTED

### VOLUME IN SMALL TREES UP

The total volume of growing stock (all commercial tree species 5.0 inches d.b.h. and larger) rose from 17.2 billion cubic feet in 1959 to 21.3 billion in 1971—a 23-percent increase. However, this increase in volume was not evenly distributed among all diameter classes. The cubic-foot volume in 6- to 12-inch d.b.h. trees rose 28 percent, while the volume in 14- to 18-inch d.b.h. trees rose 13 percent. But the volume in trees 20 inches and larger d.b.h. declined 10 percent.

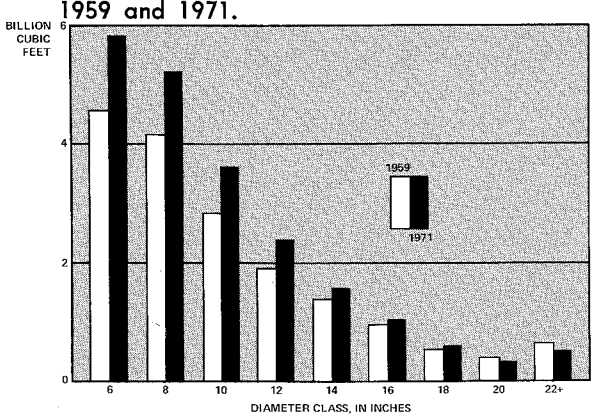
This changed distribution by tree sizes is reflected in the sawtimber trend. The volume in sawtimber trees (growing-stock trees 9.0 inches d.b.h. and larger for softwoods and 11.0 inches and larger for hardwoods) increased 19 percent—from 29.1 to 34.5 billion board feet. The volume in sawtimber trees less than 18 inches d.b.h. increased 31 percent, but the volume in trees larger than 18 inches d.b.h. declined 46 percent.

### Volume Suitable for Pulpwood Increased

The volume suitable for pulpwood totals 266 million cords (22.6 billion cubic feet). Most of this volume is in growing-stock trees —a total of 250 million cords. The other 16 million cords (6 percent of the total) are in trees too rough or too crooked to produce sawlogs (non-growing stock). Volume suitable for pulpwood in 1959 averaged about 14 cords per acre and increased to 16 cords per acre by 1971.

The total volume suitable for pulpwood increased 24 percent since 1959. The softwood component had a greater increase than the hardwood; softwoods increased 27 percent and hardwoods 18 percent. Two-thirds of the volume suitable for pulpwood in 1971 (183 million cords) is made up of the softwood species. Spruce accounts for 26 percent of the total volume for all species, and balsam fir accounts for 23 percent. Red maple, white

Growing-stock volume by diameter classes, 1959 and 1971.



pine, and sugar maple follow in descending order of abundance.

### Volume Suitable for Turnery Bolts

The wood-turning industry is an important timber-based industry in Maine. Because wood suitable for turning must be clear and rot-free, wood turners have a constant problem of finding suitable high-quality paper birch, yellow birch, sugar maple, and beech—the four principal species used by the industry.

Using forest-survey data and procurement specifications supplied by several wood-turning firms in Maine, we estimated the growing-stock volume in these four species that would be suitable for turnery bolts. About 616 million cubic feet of growing stock is suitable for turnery bolts (in rot-free trees, 8 inches d.b.h. and larger, that have 8 feet or more of the first 16 feet of bole in 2-foot clear cuttings). About 62 percent of this volume is in trees 12 inches d.b.h. or smaller.

The total suitable volume consists of: sugar maple—245 million cubic feet, yellow birch—167 million, paper birch—138 million, and beech—66 million. This volume makes up a little more than 18 percent of the total growing-stock inventory of these species. In view of the scarcity of wood suitable for turnery bolts in Maine and the present heavy cutting of these species for all products, wood turners can expect even greater difficulties in obtaining sufficient satisfactory raw material in the years to come than they have experienced in recent years.

### VOLUME PER ACRE UP

The volume of growing stock per acre rose from 1,050 cubic feet in 1959 to 1,258 cubic feet in 1971. The average volume of sawtimber per acre increased from 1,770 board feet in 1959 to 2,040 in 1971.

Forest-industry ownerships accounted for most of the increase in the average sawtimber volume per acre. Sawtimber volume per acre on forest-industry-owned lands is 2,310 board feet, well above the statewide average for all ownerships. All other ownerships combined averaged 1,790 board feet per acre, up only 5 percent from the 1959 average of 1,700 board feet per acre. This reflects a higher level of demand for sawtimber-size trees from private nonindustry lands, particularly in the southern and western sections of the State.

### VOLUME ON PRIVATE NONINDUSTRY LAND DECLINES

Combined changes in volume per acre and forest area owned brought about substantial differences in volume in each class of ownership. The sawtimber on forest-industry lands increased from 12.2 billion board feet in 1959 to 19.1 in 1971. On public ownerships sawtimber volume rose from 386 million board feet to 529 million. But on the private nonindustry lands, sawtimber volume declined from 16.5 billion board feet in 1959 to 14.9 billion in 1971. The volume of all growing stock showed similar changes except that the decline in growing-stock volume for private nonindustry lands was only 7 percent compared with the 9-percent drop for sawtimber.

### SAWLOG QUALITY DECLINES

The volume of hardwood sawlogs that met minimum specifications for log grade 1 declined from 17 percent of the total sawlog volume in 1959 to 12 percent in 1971. The volume of log grade 1 hardwood sawlogs now stands at 1.3 billion board feet.

The decline of volume in the large diameter classes, coupled with a high level of demand for quality hardwood sawlogs, appears to have brought about this situation. The log grade rules for hardwood logs for all practical purposes exclude 12- and 14-inch d.b.h. trees from producing a grade 1 sawlog because a grade 1 log must have a minimum diameter of 13 inches inside bark at the small end. It is highly unlikely that a 14-inch d.b.h. tree could have such a log. Thus an increase in the proportion of sawlog volume in 12- and 14-inch d.b.h. trees alone would bring about a decline in the proportion of log grade 1 material. As has been shown, this has happened in Maine. Also there has been a strong demand for quality hardwood sawlogs—particularly sugar maple, yellow birch, paper birch, and ash—which has also contributed to the decline.

The volume of log grade 1 material in the five major species that account for 75 percent of Maine's hardwood sawtimber removals (red maple, sugar maple, yellow birch, paper birch, and ash) decreased 35 percent. But the vol-

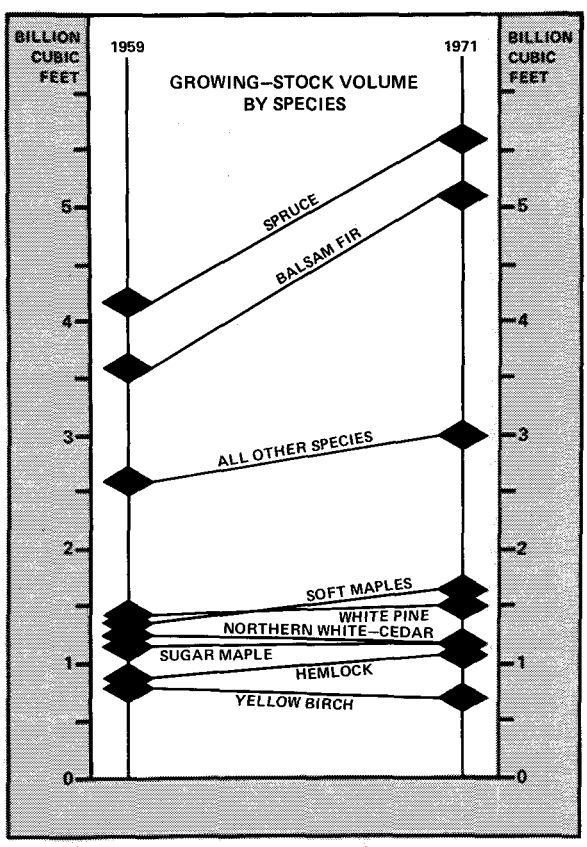
ume of grade 1 material in the other hardwood species more than doubled.

White pine is the only softwood species that was graded for sawlog quality. The volume of white pine in grade 1 sawlogs is 162.5 million board feet—less than 4 percent of the total white pine sawlog volume in Maine. In fact, grade 1 and 2 white pine sawlogs make up only slightly more than 12 percent of the total white pine sawtimber volume.

## MANY FACTORS AFFECT CHANGES IN VOLUME OF MAJOR SPECIES

Because of the variety of species, products, and forest conditions found in Maine, a discussion of changes in volume by broad groups of species, such as hardwoods and softwoods, masks many important changes in individual species. For this reason, a species-by-species discussion of changes in some of the more important commercial species seems in order.

*Spruce.* — The spruces (red, white, and black) are the most abundant species group in Maine: 5.6 billion cubic feet—up from 4.2 billion in 1959. This 34-percent increase was the largest gain of any softwood species except balsam fir. The spruces make up one-fourth of Maine's sawtimber volume. Much of this large increase in spruce is the result of a recovery from the devastating spruce budworm attacks and fires that occurred in the first quarter of the century. Many of the spruce that replaced those killed in these attacks were too small to be classed as growing stock in the 1959 survey but by 1971 they had grown to growing-stock size.



Changes in growing-stock volume by species, 1959-71.

Most of the spruce volume in Maine is found in the northern half of the State. The four northernmost counties—Aroostook, Piscataquis, Somerset, and Penobscot—together account for nearly three-fourths of the total spruce growing stock in the State.

*Balsam fir.* — The volume of balsam fir growing stock increased 42 percent to a total of 5.1 billion cubic feet in 1971. The volume of balsam fir sawtimber increased 30 percent to 4.5 billion board feet. However, because of balsam fir's characteristic small size, 90 percent of the sawtimber is in the 10- and 12-inch d.b.h. classes. Again, this large increase in fir volume, like the increase in spruce, is probably attributable to a recovery from budworm attack and fire.

Balsam fir is associated with spruce and is therefore also concentrated in the northern portion of the State. The four northernmost counties account for 80 percent of the growing-stock total.

*White pine.*—The volume of white pine growing stock (together with a small volume of red pine) increased only 8 percent since 1959 to 1.5 billion cubic feet. White pine sawtimber volume increased less than 10 percent to 4.6 billion board feet.

This small increase appears to be the result of different causes in southern and northern Maine. In southern Maine the principal cause appears to be a strong demand for white pine sawlogs. In northern Maine it appears to be the result of a combination of natural factors. First, white pine blister rust is widespread in this area and causes appreciable mortality. However, eradication of ribes plants, the alternate host of the disease and the principal control technique, is not economically feasible because of the scattered distribution of white pine in northern Maine.

Second, white pine does not reproduce well in northern Maine, except in areas that have been burned over.

*Hemlock.*—The volume of hemlock growing stock rose 30 percent between surveys and now totals 1.2 billion cubic feet. The sawtimber portion increased 28 percent. This large increase was due in part to the low level of demand for hemlock in Maine. Hemlock is most abundant in Penobscot County —280 million cubic feet—and in the Casco Bay Region—212 million cubic feet.

*Northern white-cedar.* — The volume of northern white-cedar in Maine remained essentially unchanged at 1.2 billion cubic feet. In Somerset County, however, the sawtimber volume declined 12 percent. It appears that the demand for northern white-cedar of all size classes just offsets the growth of the species. During the 12 years between forest surveys, the harvest of northern white-cedar in Maine rose from 16.9 million board feet in 1958 to 40.4 million board feet in 1970.

A large portion of this increase can be attributed to the growth of the rustic-fencing industry, which in Maine consumes primarily northern white-cedar. In 1958 rustic fencing accounted for 47 percent of the northern white-cedar harvest, but by 1970 its share had risen to 60 percent. Accompanying this growth in the rustic-fencing industry, the demand for cedar shingles and power poles, mostly from sawtimber size trees, remained strong.

*Red maple.*—Red (soft) maple growing-stock volume exceeds that of any other hardwood species in Maine and is found abundantly throughout the State. Red maple volume increased 20 percent since 1959 to 1.6 billion cubic feet in 1970. Sawtimber volume of red maple rose 24 percent during the period between surveys.

A possible explanation for the large increase in red maple volume is the low demand for this species and the high demand for such associated species as sugar maple and white pine. In many areas this has allowed red maple to dominate sites that were formally occupied by a mixture of several species.

*Sugar maple.* — Growing-stock volume of sugar (hard) maple increased 8 percent to total 1.2 billion cubic feet. Sugar maple sawtimber increased only 5 percent to 3.2 billion board feet and accounts for 29 percent of the hardwood sawtimber volume in Maine.

This species is in great demand for a variety of products, and it accounted for 18 percent of all hardwood sawtimber removals in 1970. This demand has played an important role in the decreasing relative abundance of sugar maple. In addition, the cull increment of sugar maple sawtimber (the volume of growing-stock trees in 1959 that became rough or rotten trees by 1970) was abnormally high. Harvesting practices have probably also influenced this development to some extent. When poor-quality trees are left standing, they frequently become rough or rotten trees and occupy growing space that would be better occupied by younger and healthier trees.

*Yellow birch.*—Yellow birch ranks third among the hardwoods in volume of growing stock. Since 1959 the volume of yellow birch growing stock has declined 8 percent to 744 million cubic feet.

The volume of yellow birch sawtimber declined 10 percent to 1.6 billion board feet. This decline was probably the result of a combination of factors. Yellow birch is in great demand for such products as veneer and turnery bolts as well as for lumber. The removals of yellow birch sawtimber during the period between surveys exceeded growth 3 to 1. Cull increment of yellow birch is also abnormally high. This may be the result of the birch dieback epidemic that occurred in the 1950's. Many trees that did not succumb to the disease were heavily damaged. This damage provided opportunity for rot, and thus many of these trees became non-growing stock.

*Paper birch.* — Growing-stock volume increased 15 percent to 740 million cubic feet in 1971, and sawtimber volume increased 17 percent. The increase in paper birch volume was not evenly distributed throughout the State. Paper birch growing stock increased less than 10 percent in Hancock County and in the Capitol and Casco Bay regions. Washington, Aroostook, and Somerset Counties registered gains of 20 to 30 percent. However, paper birch sawtimber volume increased in all counties except Hancock, where it remained unchanged. This variation by sampling units is probably the result of past cutting practices that do not favor birch regeneration, the absence of fires, and the different levels of demand for paper birch in different sections of the State.

## NET GROWTH EXCEEDS TIMBER REMOVALS

Growing-stock volume increased 4.0 billion cubic feet during the 12-year period between surveys to 21.3 billion cubic feet in 1971. This increase resulted from less timber removal than net growth during the period—an average annual net change of 335 million cubic feet. Sawtimber volume increased 5.4 billion board feet during the same period to 34.5 billion board feet. Total sawtimber removal was less than net growth, and the average annual change was 452 million board feet. As pointed out earlier, although total volume of the average annual net growth exceeded total average annual removals, this is not true for some species whose removals were greater than net growth.

### VOLUME OF INGROWTH IS LARGE

The average annual change in growing-stock volume and sawtimber volume is the composite of several components: growth on initial volume, ingrowth, change in merchantability (cull-tree increment), mortality, and timber removal. An unusual change in one or more of these components may account for an unusual difference in the average annual change. For example, one species may have had unusually high mortality, while another may have had unusually high cull-tree increment.

For most species in Maine, ingrowth is one of the most important components. The volume of ingrowth trees (growing-stock trees that were less than 5.0 inches d.b.h. on the initial survey and that grew to 5.0 inches d.b.h. and larger) made up 57 percent of the average annual gross growth of growing stock. Ingrowth accounts for such a large portion of gross growth because of the long period between surveys and because the mortality and cull increment of some species were unusually high. If this volume loss were cut in half and survivor growth of growing stock were increased accordingly, the ingrowth volume would have been less than 50 percent of gross growth.

Also, spruce and balsam fir (the two major species) show a high proportion of ingrowth as a result of recovery from the spruce budworm epidemic around 1920. Many young spruce and fir that seeded in in the 20's and 30's after this attack reached growing-stock size between 1959 and 1971.

Mortality of growing-stock trees and cull-tree increment together reduced the average annual gross growth by almost 30 percent. The volume for each of the components of average annual net change in growing stock is shown below:

| | *Million cubic feet* | *Percent of gross growth* |
|---|---|---|
| Survivor growth of growing stock (accretion) | 386.8 | 43 |
| Volume and growth of trees that became poletimber (ingrowth) | +507.4 | +57 |
| Average annual gross growth | 894.2 | 100 |
| Cull-tree increment | −133.7 | −15 |
| Crowing-stock tree mortality | −123.7 | −14 |
| Average annual net growth | 636.8 | 71 |
| Average annual removals | −301.4 | −34 |
| Average annual net change | 335.4 | 37 |

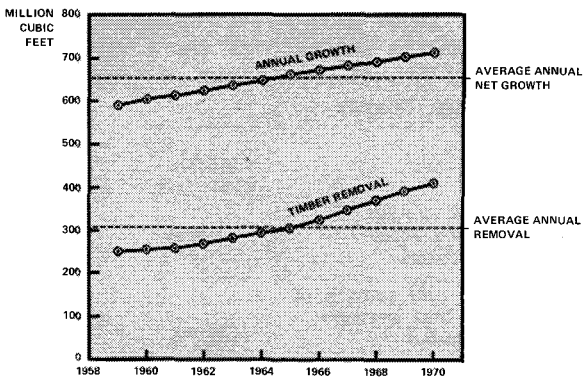
Ingrowth volume of growing-stock trees that grew into the sawtimber-size class also made up a very large percentage (62 percent) of the average annual gross growth of sawtimber. The volume of trees that died and the volume of trees that became non-growing stock reduced the volume of the average annual gross growth of sawtimber 34 percent. Average annual net growth of 1,063 million board feet exceeded the average annual removal of 610 million board feet and resulted in an average annual change of 453 million board feet.

### REMOVALS INCREASE FASTER THAN GROWTH

Analysis of the changes that are taking place in the timber inventory of Maine shows that, even though annual net growth exceeded removals, removals are increasing faster than growth. This rate of increase is three times faster than the rate of increase in growth. Timber removal of growing stock as a percent of annual net growth in 1970 was 58 percent, as compared to 44 percent in 1959.

Annual net growth of growing stock for 1970 was 711 million cubic feet, or 12 percent more than the average annual net growth for the 12-year period. Timber removals of grow-

**Average annual growth and removals and trends in growth and removals, 1959-70.**



ing stock in 1970 totaled 409 million cubic feet and were 36 percent greater than the average annual timber removals for the period. Even though the rate of increase for timber removals is greater than the rate of increase of annual net growth for all species together, more timber of certain species—such as hemlock and red maple—could be cut if markets were readily available.

The situation for softwood growing stock is somewhat different than that for hardwoods. The annual net growth for softwoods in 1970 was 550 million cubic feet or, expressed as an annual rate of the inventory, it was 3.7 percent. Softwood removal in 1970 (275 million cubic feet) was 50 percent of the net growth. In contrast, the annual net growth for hardwood growing stock in 1970 was 161 million cubic feet; this was a rate of 2.5 percent. Hardwood removal in 1970 (134 million cubic feet) was 83 percent of the net growth.

Spruce and balsam fir growing stock had the greatest volume of net growth—404 million cubic feet. Together they accounted for 57 percent of the total net growth in 1970. The volume of timber removals in 1970 for these species totaled 148 million cubic feet and made up 36 percent of the total removals.

The ratio of growing-stock removals to net growth was not as favorable for several other important species as it was for spruce and fir. Net growth and removals were about equal for white pine and sugar maple, and removals were greater than net growth for some less abundant species such as oak, ash, and yellow birch.

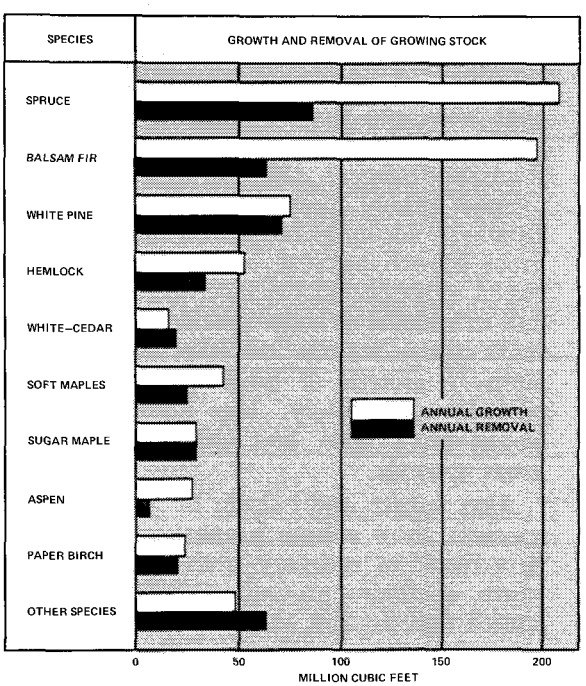
The sawtimber portion of growing stock generally had a less favorable relationship between annual net growth and timber removals than for growing stock as a whole. Removals of sawtimber volume were greater in relation to net growth than removals of growing-stock volume. Sawtimber removals as a percent of net growth in 1970 were 80 percent, while growing-stock removals were only 58 percent.

Net growth of sawtimber in 1970 was 1,622 million board feet, and sawtimber removals totaled 1,299 million. Sawtimber removals as a percent of annual net growth (80 percent) were considerably greater than in 1959 when they made up 60 percent.

Like growing stock, the sawtimber removals and net growth comparisons differed according to species groups. In 1970 softwood sawtimber removals (878 million board feet) were 28 percent below the net growth of 1,224 million board feet; hardwood sawtimber removals (421 million board feet) were 6 percent above the net growth of 398 million board feet.

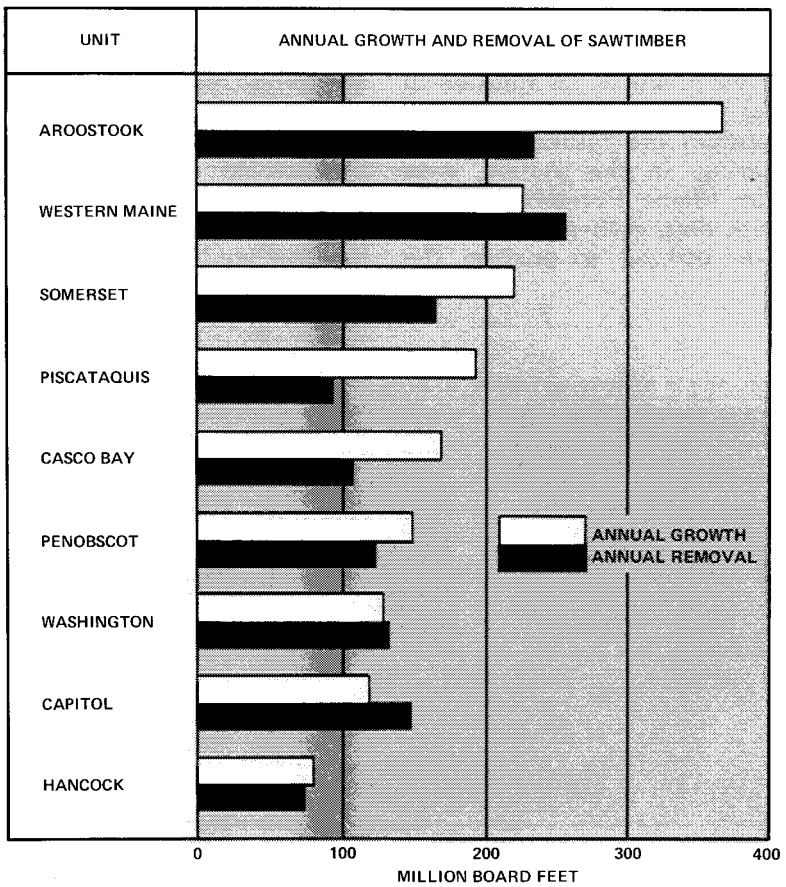
Sawtimber removals and net growth for 1970 also differed according to the geographic unit in the State. In five of the sampling

**Net growth and removals of growing stock by species, 1970.**



units, sawtimber removals averaged 60 percent of the net growth; however, in two sampling units—Washington and Hancock Counties—removals and net growth were about equal, and in the other two sampling units—Western Maine and the Capitol Region—removals of sawtimber volume exceeded net growth almost 20 percent.

Net growth and removals of sawtimber, by geographic units, 1970.



# Timber-Products Output

The timber-products output estimates in tables 26 and 27 should not be confused with the estimates of annual timber removals shown in tables 19 and 20. Timber products output is that portion of total timber removals that was used for products. In addition to timber removed for products, timber removals include logging residues and "other removals" such as land clearing. In this section, data obtained from the Maine Forestry Department, together with data gathered as part of the resurvey, were utilized to analyze the 1970 timber harvest and output of timber products.

Maine has a longer continuous history of timber harvesting than any other major timber-producing state in the country. The first sawmill of record built in Maine was built in 1634; however, it is believed that one was built before that, in 1623. Maine dominated the lumber industry during the colonial period, but by 1839 New York took over the lead. Nonetheless, Maine remained one of the top five lumber-producing states until 1869,

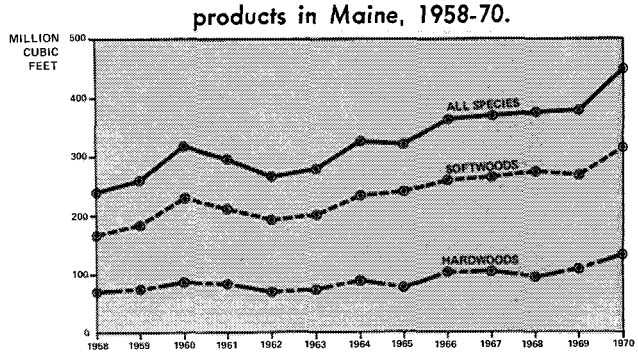
when logging had moved into the Lake States. In 1946 the production of lumber in Maine exceeded that in each of the five states—Michigan, Pennsylvania, New York, Wisconsin, and Indiana—that had bested it in 1869. Many other states have had their brief heyday of timber production, but Maine has kept on producing a steady stream of timber products for over 250 years.

The production of timber products in Maine reached a low point during the depression, but since then it has increased steadily. In 1958 the total production of timber products in Maine stood at 243 million cubic feet; by 1970 production was up to 437 million. This represents an increase of about 80 percent over the 1958 production. Timber production showed a generally steady increase from 1958 to 1970 for softwoods, hardwoods, and for both combined.

The production of timber products in Maine, 1958-70.

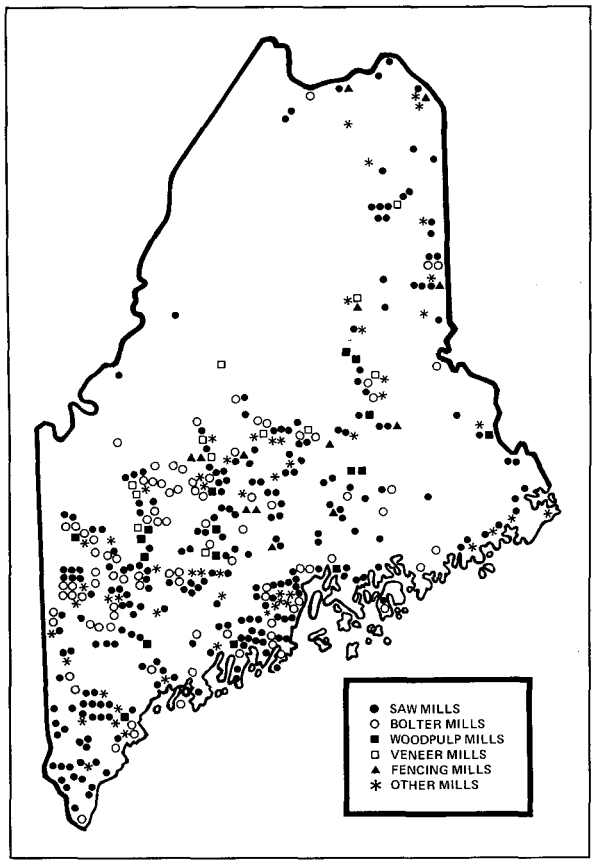


In 1970 approximately 426 primary wood-using plants were in operation in Maine. These included sawmills, bolter mills, woodpulp mills, veneer and plywood plants, fencing manufacturers, and a variety of other plants. Most wood-processing plants in Maine are small locally owned businesses.

## PULPWOOD

In 1970 almost 3,221,000 cords of pulpwood were harvested from Maine forests. An additional volume equivalent to 248,000 cords was produced in the form of chipped sawmill slabs and edgings. Both forms of pulpwood — roundwood and pulp chips — totaled 3,469,000 cords in 1970. This is more than double that for 1958.

Distribution of primary wood-processing plants, 1970.

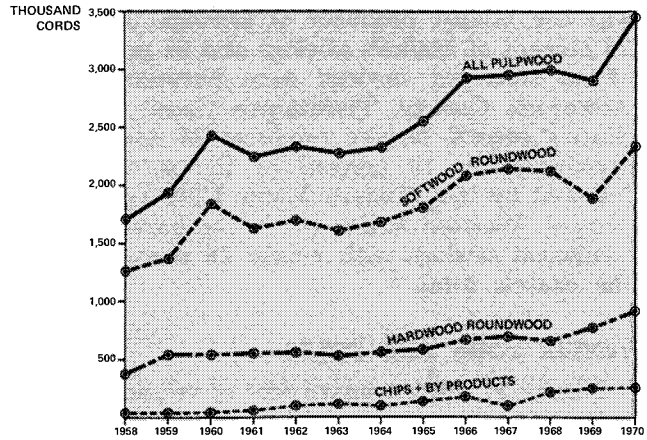


Pulpwood is Maine's most important timber product. Of the 408 million cubic feet of wood harvested in 1970, 274 million cubic feet, or 67 percent, was pulpwood. The volume harvested for pulpwood was two and one-half times the volume harvested for sawlogs.

The 17 woodpulp mills in Maine received a total of 3.4 million cords of roundwood in 1970. Of this total, 3.1 million cords came from Maine and 337 thousand cords was shipped in from other states and provinces. A total of 111 thousand cords harvested in Maine was shipped to woodpulp mills outside the State.

Aroostook County leads the geographic units in the harvest of pulpwood with 706 thousand cords, or nearly 22 percent of the total harvest in 1970. Although Aroostook County leads the State in the total harvest

The trend of pulpwood production in Maine, 1958-70.



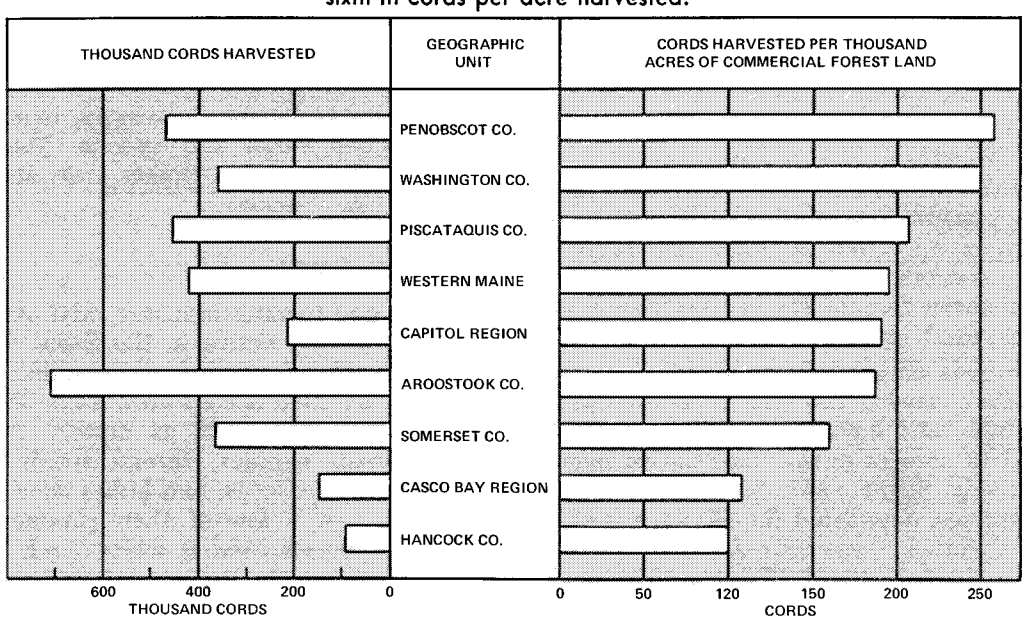
of pulpwood, a comparison of the 1970 pulpwood harvest per 1,000 acres of commercial forest land in each unit puts Aroostook County's lead in perspective. Of the nine geographic units in Maine, five harvested more pulpwood per thousand acres of commercial forest land than did Aroostook County. In fact, Aroostook County's harvest of 188.5 cords per thousand acres is slightly below the statewide average of 190.7 cords per thousand acres.

Since 1958 the volume of pulpwood chips has risen, almost without interruption, from only 35 thousand cords. Slabs and edgings, formerly a residue left from the manufacture of lumber, have become an additional source of income to sawmill operators, and they have made possible the closer utilization of the timber resource. In recent years some chipping plants have begun to chip limbs and tops of trees harvested for sawlogs. This also increases the proportion of each tree harvested that is recovered as usable wood.

Softwood species accounted for over 72 percent of the round pulpwood produced in Maine in 1970. Spruce and fir were by far the leading species. About 59 percent of the pulpwood harvested in 1970 was spruce and fir. Hemlock, white pine, and tamarack made up the remaining 13 percent.

Hardwood species accounted for 28 percent of the round pulpwood harvest in both 1958 and 1970. The percentage of hardwood has varied from a low of 22 to 30 percent of the total harvest in the intervening years. The factors that limit the use of hardwood are the pulping processes used by Maine pulpmills and the final product of the paper mills. As existing mills are modernized and new ones are constructed, we can expect changes in the pulping processes used and the paper products manufactured, which will favor greater utilization of the hardwood species.

Although Aroostook County ranks first in total cords of pulpwood harvested, it ranks sixth in cords per acre harvested.

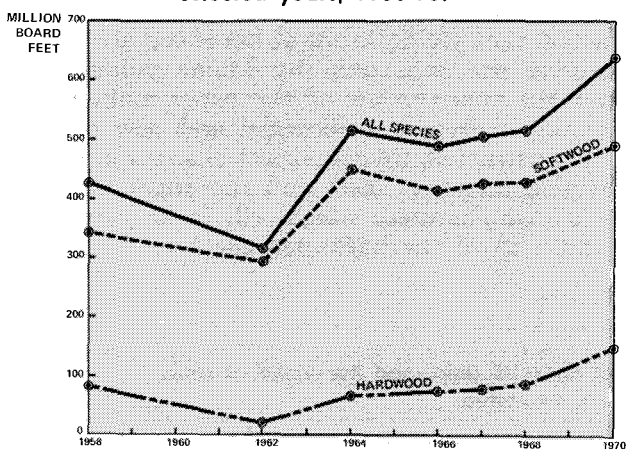


## LUMBER AND SAWLOGS

Lumber production in Maine reached a record high of 1.1 billion board feet in 1909 but declined steadily to its record low of 200 million board feet in 1932. Since 1932 the production of lumber in Maine has been on the increase. By 1953 lumber production was up to 589 million board feet.

In 1958 Maine harvested 424 million board feet of sawlogs (the raw material for the lumber industry). Since 1958 the harvest of sawlogs has risen nearly 50 percent to 634 million board feet in 1970. Approximately 250 million board feet of the Maine sawlog harvest of 1970 were shipped to Canada and neighboring states for milling.

Sawlog production in Maine, selected years, 1958-70.



In 1970 Maine had fewer sawmills—235—but they were larger on average than the 669 mills that operated in 1958. In 1970 the average sawmill in Maine produced about 1.8 million board feet of lumber compared with 600 thousand in 1958.

Softwoods accounted for about 77 percent of Maine's sawlog harvest in 1970. Spruce, white pine, and balsam fir accounted for 29, 22, and 13 percent of the total sawlog harvest respectively. Sugar maple, which led the hardwood species, accounted for 10 percent of the total. Together these four species accounted for over 74 percent of Maine's 1970 sawlog harvest.

By geographic units, Aroostook County was the largest producer of sawlogs. About 28 percent of Maine's sawlogs and 31 percent of its softwood sawlogs were harvested in Aroostook County. Piscataquis County, the State's second largest producer of sawlogs, accounted for 19 percent of the softwood, followed by the Western Maine Unit with 11 percent. Western Maine led in the harvest of hardwood sawlogs with nearly 26 percent of the State's total.

## VENEER LOGS AND BOLTS

Nearly 37 million board feet of veneer logs and bolts were harvested from Maine's forests in 1970, down from 48.5 million board feet in 1969. Fluctuation has been a characteristic of this industry during the 1958-70 period. In 1958 the harvest of veneer logs and bolts was 43 million board feet. By 1963 it had risen to 51.3 million board feet; in 1968 it dropped to 49.7 million.

Nearly all the wood used in Maine's veneer industry is hardwood. The principal species used are white birch, sugar (hard) maple, and yellow birch. White oak, aspen, basswood, beech, and some white pine are also used.

Twelve veneer plants, owned by 10 companies, were operating in 1970. Three plants produced hardwood plywood, one produced face or panel veneers, and the other eight produced specialty veneers. Specialty veneers is the name given to a vast array of products produced from veneers that are neither containers nor plywood products. Many of these are products stamped with cutting dyes from sheets of hardwood veneer. These include such items as tongue depressors, tooth picks, and wooden forks and spoons. Maine has more specialty veneer plants than any other state in the Nation.

## TURNERY BOLTS

The wood-turning industry, with 38 plants in 1970, is very active in the State. In 1958 this industry consumed 41.9 million board feet, and in 1970 it consumed 44.5. Turneries produce such products as dowels, furniture parts, brush handles, thread spools, textile bobbins, billiard cues, and ladies shoe heels—to name just a few of their products. The principal species used is white birch. Yellow birch, sugar maple, aspen, and beech are also important.

Trees of suitable quality and species for turnery bolts are often harvested with sawlogs or pulpwood and then resold to the turneries because they bring higher prices as turnery bolts than as either sawlogs or pulpwood. For this reason the production of turnery bolts is not shown as a separate item in table 26 and other tables.

The bolts are sawed into blanks at bolter mills. A bolter mill is a small sawmill equipped to saw logs up to 8 feet in length. In 1970 there were 93 bolter mills in Maine, compared to 131 in 1958. Not all bolter mills supply the turning industry. Many produce furniture and novelty squares, lobster-trap stock, pallet stock, box boards, and the like.

## OTHER INDUSTRIAL TIMBER PRODUCTS

Four products—sawlogs, pulpwood, veneer logs and bolts, and turnery bolts—accounted for 95 percent of the wood harvested in Maine in 1970. The remaining 5 percent went into such products as cooperage logs and bolts, posts, poles, piling, fuelwood, and others too numerous to mention.

The cooperage industry in Maine is declining. In 1958 the consumption of cooperage logs and bolts was 1,633 thousand board feet. By 1970 consumption had dropped to 545 thousand feet. Maine's cooperage industry uses more softwood than hardwood; about 330 thousand board feet were used in 1970. The cooperage industry in Maine makes slack cooperage, mainly barrels and tubs for potatoes, fish, and lobsters. Some manufacture cooperage novelties such as wooden sand pails and furniture.

The rustic-fence industry has shown substantial growth over the past 13 years. In 1958 this industry consumed 7.9 million board feet of northern white-cedar harvested from Maine forests. In 1970 consumption of Maine's white-cedar stood at 24.4 million board feet—up 300 percent. The estimates of fence-post production in table 26 also reflects the growth of this industry. In 1970 Maine produced 648 thousand posts, almost all softwood; and nearly all of this was northern white-cedar, compared with 123 thousand posts that were produced in 1958.

## FUELWOOD

In 1970 fuelwood production totaled 324 thousand cords, compared with 264 thousand in 1958. Of this total, 105 thousand cords were produced from wood-industry residues like sawmill slabs and edgings and 29 thousand cords came from dead trees, rough trees, rotten trees, tops, shade trees, and other nongrowing-stock material. Thus only 190 thousand cords (or less than 59 percent of the total fuelwood production) came from growing stock that was harvested for fuelwood.

In recent years the role of fuelwood has changed from a necessity to a luxury. Fuelwood was once an important heating fuel, particularly in rural areas, but more and more fuelwood today is used in fireplaces and stoves for its pleasant effect rather than for its heat value. This trend may account for the increase in fuelwood production.

## THE ECONOMIC IMPORTANCE OF MAINE'S TIMBER RESOURCE

Based on average prices for species and products, the total stumpage value of the 1970 timber harvest from Maine's forests amounted to nearly $27 million. Stumpage value is the value of standing timber before harvesting. After harvesting and delivery to primary wood processing plants such as sawmills, woodpulp mills, and veneer mills, this timber was worth $118 million.

A common measure of the economic impact of raw material is value added in manufacture. Value added is the difference between the cost of goods and services purchased by a manufacturer and the value of the products sold. It is value added that provides the money for wages, salaries, profits, taxes, and the like. Value added can be broken down as being attributable to each of the component goods used in the manufacture of a final product. For instance, only part of the value of an upholstered chair is attributable to wood, other portions are attributable to textiles, metals, finishes, fuel, electric power, and packaging.

By means of value added that is attributed to timber, it is possible to estimate the economic impact on Maine's economy of the $27 million dollars worth of stumpage harvested in 1970. Value added attributed to timber for the major steps between the stumpage and the final consumer were calculated for Maine in 1958 by Hair *(3)*. Although these estimates are now 13 years old, in all probability the ratios between them have changed little over the years. By applying these ratios

we can estimate that the timber harvested in 1970 as final products was worth $413 million to Maine's economy. Taking this increase step by step, harvesting added $46 million. Primary manufacturing—converting logs and bolts into lumber, pulp, veneer, and similar products — added $201 million. Secondary manufacturing — remanufacture into finished goods—added $59 million. Construction added $41 million, and transportation and marketing added $39 million.

These values added were added in Maine only. Some of the timber harvested and some of the primary products produced in Maine are shipped to other states or to Canada for manufacturing into final products. The value added to these intermediate products in these other states or provinces appears as value attributable for them, even though the timber originally came from Maine. For instance, Massachusetts has a value added attributed to timber that is twice as high as for Maine, even though Maine harvests about 17 times more timber than Massachusetts. This is because the timber-base industrial activity of Massachusetts is concentrated in secondary industries that manufacture such final products as furniture, homes, paper boxes, and so forth.

In 1970 the total value of all manufactured products produced in Maine was nearly $2.5 billion *(5)*. The two major timber-based industries of the State accounted for $929 million, or 38 percent of the total. The paper and allied products industry is the largest manufacturing industry in Maine. In 1970 its total product value stood at $714 million. Lumber and wood products ranked fourth, with a total product value of $215 million.

(Paper and Allied Products is U.S. Bureau of the Census Standard Industrial Classification (SIC-26); it includes pulpmills, papermills, paperboard mills, and paper fabricators. Lumber and Wood Products (SIC-24) includes logging camps and contractors, sawmills and planing mills, veneer and plywood, cooperage, millwork, and other wood products except furniture.)

One of every four people employed in manufacturing in Maine in 1970 was employed in the timber-based industries. These people received gross wages totaling $201 million dollars, or nearly 30 percent of the State's manufacturing payroll.

The value and importance of only one product of Maine's forests—timber—has been presented. The value of the other products is very difficult to quantify in terms of dollars. If it were possible to quantify and add the values of water supply and its quality, wildlife, recreation, and scenery to the value of timber and the timber-based industries there is little doubt that the total would be staggering. It is small wonder that Maine's forests have been called her most valuable natural resource.

## HOW MUCH TIMBER COULD BE HARVESTED?

The primary objective of the forest survey of Maine was to measure the volume, condition, composition, rate of growth and removals, and extent of Maine's timber resources. No attempt has been made to determine the volume of timber that can be bought or sold on the open market.

In 1970 the total net annual growth of growing stock in Maine was 711 million cubic feet. The volume of growing stock removed was 409 million cubic feet. This leaves a difference of 302 million cubic feet of growth over removals. This difference is often thought of as the volume of additional timber that could be harvested annually without detriment to the growing-stock base. But the actual volume that could be harvested statewide is usually much less than this difference, for a variety of reasons.

When the volume of growth over removals is examined, we find that many factors tend to limit the volume of timber that may be bought or sold. Forest-industry lands grow about 383 million cubic feet per year. Even though forest industries from time to time sell some of their timber on the open market, it is usually available only to the industrial owner. By virtue of the fact that he owns the land, the industrial owner always has first call for the timber on his lands.

Another 315 million cubic feet of growth is in farmer and miscellaneous private ownerships. Many of these owners may be unwilling to sell timber under any circumstances. Others may be unwilling to sell at current market prices, or they may set conditions on harvesting that would make harvesting unprofitable.

Several studies have been undertaken to determine the attitudes of private forest own-

ers and their willingness to harvest timber. Miller and Canham *(6)* found that in New York State 27 percent of the owners were unwilling to harvest timber. In the Georgia Piedmont Region, Holemo and Dyson *(4)*, found that the owners of 34 percent of the region's forest land were unwilling to harvest timber. In a study of forest land owners in the Upper Peninsula of Michigan, Robert N. Stone (unpublished doctoral thesis, University of Minnesota, 1969) concluded that private nonindustry forest land owners indicated timber production as a primary objective for owning forest land only 28 percent of the time. Yet, in spite of this, these ownerships yielded a high proportion of the timber harvest.

A somewhat similar situation may also exist in Maine, as indicated in table 21. It is often said that many private nonindustry landowners in Maine are not interested in timber production, and some are opposed to timber harvesting. Yet private nonindustry forest lands accounted for 44 percent of the annual net growth in 1970, but they accounted for 52 percent of the timber removals. If in fact some ownerships are excluded from harvesting by owner attitude, the remaining ownerships are being harvested more intensively than table 21 would indicate. This also indicates that the conclusions reached by Stone in Michigan may also apply to Maine. Although none of the studies discussed above pertains specifically to Maine, they clearly indicate that the attitudes of forest landowners can strongly influence how much timber could be harvested.

A substantial volume of growing stock may be unharvestable for economic reasons. Areas with too little volume per acre, stands that are too far from market, or too wet, or too steep, cannot be harvested profitably. On other areas the timber may be too small to be marketable, or the timber may be predominantly of a species or quality that is unsalable.

Forest-management policies also influence the volume of timber that may be harvested. In many instances forest managers may put off harvesting timber in order to build up the stocking of the stands. In other cases the management objective may be to produce quality sawlogs, so salable timber may be withheld from the market while it increases in both size and quality. In some cases more timber may be made available than is being grown annually on an area because a management need is to reduce the stocking per acre to the optimum level or because of a need to alter the species composition of the area.

The tables in the appendix of this report provide a guide for those who wish to locate timber supplies. They do not, nor can they, answer the question: How much timber can be bought or sold at current prices? Taken together, the appendix tables can serve to point out areas where timber may be available, and that may warrant further investigation by the prospective buyer.

# More Than Wood

This report is concerned primarily with Maine's forests as a supplier of wood and fiber. But these forests provide much more than wood.

## WATER

Though forests themselves do not supply water, they do have a profound effect on what happens to the water that falls on them. The forest cover intercepts the rainfall and cushions the impact of falling rain on the soil. Tree litter on the forest floor decomposes to form humus, which, as well as returning nutrients to the soil and providing a growth medium for thousands of plants and animals, acts like a sponge to absorb water and prevent excessive runoff. Tree roots increase the porosity of the soil and permit water to penetrate more readily.

The map of Maine attests to the fact that the State is amply endowed with water. Lakes and ponds linked by numerous rivers and streams are everywhere. But, were it not for the existence of a healthy viable forest cover, these same lakes and streams could easily flood and cause millions of dollars of damage. Each year over 19 billion gallons of water in the form of rain and snow fall on the State of Maine. It is in large part the forests that keep the State's streams and lakes full most of the year, helping to regulate the flow of the precipitation once it is on the ground.

## RECREATION

Recreation is big business in Maine. The Maine Department of Economic Development estimates that recreation is a $450-million industry. The vast forests of Maine have always played a major part in attracting recreationists. It is estimated that in 1970 over 1.7 million people visited Maine State Parks, most of which boast a forest atmosphere. These 1.7 million represent only a fraction of the total who sought recreation in Maine's forests. Many more visited commercial camping areas or the campsites maintained by many of the large landowners. Also many visited the 193 campsites maintained by the Maine Forestry Department in the unorganized townships. We have no count of the thousands who visited lodges and hotels or who just toured through the State enjoying the scenery.

With so many forested lakes and streams, it is not difficult to see why canoeing has become such a popular pastime in Maine. Each year thousands travel the State's waterways. In 1970 an estimated 5,000 persons traveled on the Allagash Wilderness Waterway, one of the most spectacular and popular canoe trips in North America.

## WILDLIFE

Wildlife is an important part of the forest community. Maine's forests support about 13 thousand moose. The State's deer herd is estimated at about 250 thousand and black bears number about 7 thousand. In addition the State is well endowed with ruffed grouse (partridge), cottontail rabbits, varying hare (snowshoe rabbits), racoons, beaver, otter, porcupines, and many many others. The State's lakes and streams provide some of the best fresh-water fishing in the East. Landlocked salmon and trout lead the list.

Hunting and fishing are big business in Maine. An estimated 380 thousand people participated in these outdoor sports in 1970. The Maine Department of Fish and Game estimates that hunters and fishermen spend over $43 million annually on licenses, equipment, lodging, meals, and transportation.

Timber production and other uses of the forest have existed side by side in Maine for many years.

## TIMBER AND THE OTHER USES

The forests of Maine have produced timber products for nearly 250 years; yet at the same time they have become a recreation mecca, have generally prevented erosion and flooding, and have maintained healthy and vigorous wildlife populations. Maine provides an excellent example of many uses and users of the forest existing side by side in general harmony.

Many large landowners welcome recreationists to their lands. Some even provide special recreation maps. All that is asked is that the visitor obey a few rules and at times pay a nominal road-use fee. Many recreationists often think they are in a vast untouched wilderness when in fact they may be camping in an area that has provided three or four timber crops.

Often, when timber is harvested in Maine, some patches are left untouched for deer yards to provide protection and food for deer in the winter months. Logging roads are often seeded to grasses and clover to prevent erosion as well as to provide food for wildlife.

# Timber-Supply Outlook

Preceding sections of this report have described the timber-resource situation in Maine as of 1971. They show that the growing-stock inventory has increased 23 percent since 1959 and that timber removals in 1970 were slightly more than 57 percent of annual net growth. But they also show that timber removals have been increasing at a rapid rate and that for several important species in many areas of the State removals either exceeded growth or were extremely close to exceeding growth.

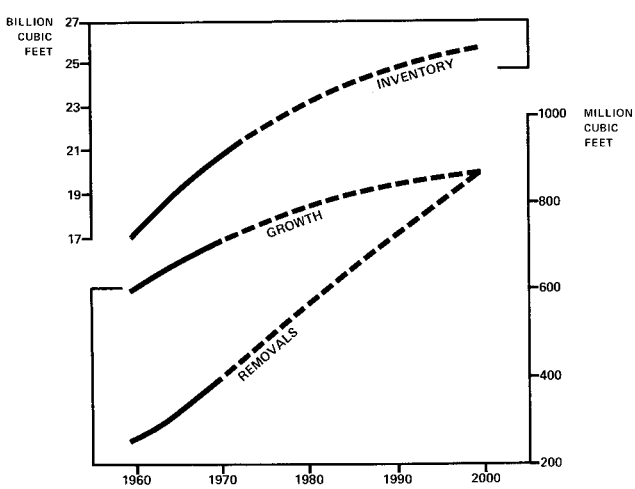
The main question to be answered is: What might be the future timber-supply situation in Maine? In answer to this question, we will present two separate projections, which proceed from different basic assumptions. However, underlying both of these projections are three common assumptions: (1) the total area of commercial forest land in Maine will remain basically unchanged; (2) growth rates based upon the average annual net growth between surveys will hold for the next 30 years; and (3) there will be no major increase in the level of forest management in Maine during the next 30 years.

## FIRST PROJECTION: GROWTH EQUALS REMOVALS IN 2000

The first projection is based on the objective that the annual net growth and removal of growing stock will be brought into balance in 30 years. Growth now totals 710.8 million cubic feet per year, and removals total 408.7 million cubic feet. They would come into balance at 860 million cubic feet. Under this projection, the total inventory of growing stock would increase from 21.3 billion cubic feet in 1970 to 25.7 billion in 2000.

For this to be accomplished, the rate at which timber removals has been increasing in recent years will taper off until removals coincide with growth in the year 2000.

First projection: growth equals removals in 2000.



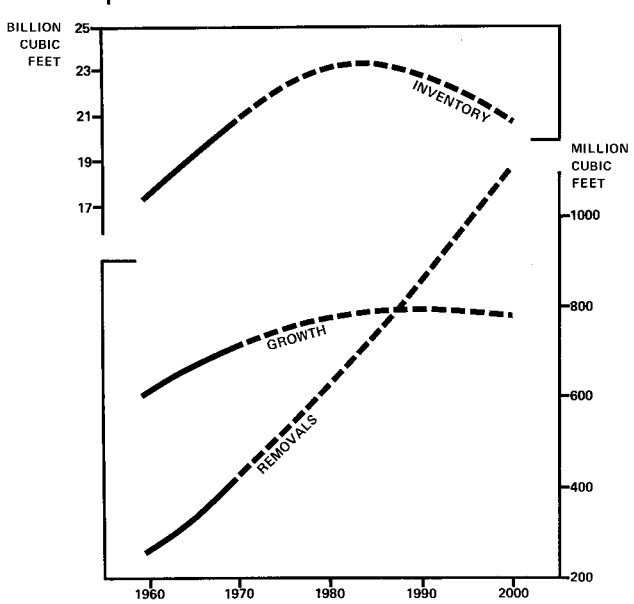
## SECOND PROJECTION: REMOVALS FOLLOW 1958-70 TREND

This projection is based on the assumption that the trend of timber removals for 1958-70 will continue through the next 30 years. During the 12-year period between surveys, softwood removals have increased about 4.5 percent per year while hardwood removals have increased about 5.9 percent per year.

Even though present-day timber removals in Maine are only 58 percent of annual net growth, this projection shows that there may be little room for complacency. Under this projection, total removals of growing stock would increase from 408.7 million cubic feet in 1970 to nearly 1.1 billion in the year 2000. Annual net growth would increase only from 710.8 million cubic feet in 1970 to 768 million cubic feet in 2000. At the same time the total growing-stock inventory in the State would decrease from 21.3 billion cubic feet in 1970 to 20.6 billion in 2000. Thus by the year 2000 Maine would find itself in the unenviable position of harvesting about 335 million cubic feet more each year than is grown.

This situation becomes even more serious when hardwoods are examined. If present trends in hardwood removals continue, they will exceed growth by 1973, according to this projection. At the end of the 30-year period, hardwood removals would be nearly three times growth. Overcutting does exist now in many important hardwood species and in certain localities. This is particularly true in western and southern Maine.

Second projection: removals continue on present trend to 2000.



Does this projection mean that the future of Maine's hardwood timber resource is in doubt? The answer to this question depends on several considerations.

First, it seems unlikely that the removals of hardwoods will continue to increase at the 1958-70 rate. A growing scarcity of the commercially important hardwood species will tend to dampen the growth of industries that consume these species.

Second, and perhaps most important, the present hardwood growth rate in Maine is abnormally low at only 2.5 percent of the inventory. The reason for this appears to be the past history of hardwood timber harvesting in Maine. Many hardwood stands in the State have been high-graded repeatedly. That is, only the best-quality timber has been removed. The result is that present hardwood stands in Maine, particularly northern hardwood stands, are heavily stocked with slow-growing, poor-quality trees. So little hardwood timber in Maine is in managed stands that for all practical purposes one can say that generally in Maine hardwoods are not managed. Given active management of Maine's hardwood resource, it appears reasonable to conclude that the average annual growth rate would be raised from the present 2.5 percent to 3.5 and possibly 4 percent. This would, of course, take time and a wide-spread effort at timber management. Thus, it appears conceivable that, through a concentrated effort, Maine could continue to grow more hardwood than is harvested for several years to come. But, in the absence of such an effort, the day when removals exceed growth in hardwoods may not be far off.

Although this projection shows that softwood removals will exceed growth after 1993, the situation here does not seem as potentially serious as in the case of hardwoods. The reasons for this appear to lie mostly in the nature of the two species groups and in the ownership pattern that prevails in each.

The great bulk of the softwood growing stock in Maine is in the northern portion of the State and is held by owners, both industrial and nonindustrial, who have an ac-

tive interest in timber management. Also, the softwoods are typically held in large tracts, which facilitates management. In contrast, the hardwoods in Maine are usually found in small tracts held by owners who often have only a secondary interest in forest management. At present most forest management in the spruce-fir region can be described as extensive rather than intensive. Present demands for softwood are being met with little additional effort in timber management. Given the nature of the owners and the areas that they own, there appears to be little question that, as annual removals of softwood begin to approach annual growth, timber-management activities will be increased and softwood removals will not exceed growth. Such a statement cannot safely be made for hardwoods because of the fragmented nature of the ownerships and because of the past history of timber harvesting on these ownerships.

## WHY TIMBER REMOVALS MAY EXCEED GROWTH

An aggregate projection such as this second projection masks many individual problems. Removals in 1970 exceeded growth in several important hardwood and softwood species (table 20). Northern white-cedar, northern red oak, white ash, and yellow birch growing stock and sawtimber were overcut. The removal of yellow birch sawtimber in 1970 was more than 3 times the growth. White pine, sugar maple, and beech sawtimber were also overcut in 1970. The reason that total removals did not exceed growth in 1970 is that the overcutting of these species was offset by the growth of species such as red maple and hemlock, for which only limited markets exist.

A pertinent explanation of why timber removals may exceed growth in Maine, as indicated by the resurvey, is that Maine's forests are producing timber at a rate much below their theoretical potential. Commercial forest land is growing timber at the rate of 42 cubic feet per acre per year. Forest-industry lands average 46 cubic feet per acre per year while farmer and other private lands average 38 cubic feet. Yet, almost 80 percent of the commercial forest land in Maine is theoretically capable of producing over 50 cubic feet per year, and 45 percent is capable of growing 85 cubic feet or more per acre per year.

The reason why growth is so far below its potential in Maine is that many stands have a large proportion of their volume in rough or rotten trees. This is particularly true for the hardwood stands. In fact, 36 percent of all hardwood trees on commercial forest land are either rough or rotten trees (table 11). A look at stocking levels by stand components shows the role of these non-growing-stock trees in reducing growth. When all live trees are considered, 54 percent of Maine's commercial forest land is overstocked. But, when only growing-stock trees are considered, this percentage drops to 16 percent. Overstocked means that there are too many stems per acre to permit maximum growth. Therefore a real need exists to reduce the non-growing-stock component of Maine's timber stands, particularly hardwood stands, so they can produce timber at a rate nearer their potential.

# Management Opportunities

The previous section indicated that if present growth and timber-removal trends continue, removals could exceed growth in the foreseeable future. The previous section and earlier sections have pointed to the fact that, for many important species, removals already exceed growth.

The results of this survey show that much of Maine's commercial forest land needs active management. If Maine's timber-based industries are to continue to grow at a rate comparable with recent years, these areas *must* be managed. Management needs appear to be greatest in the southern and western portions of the State, where most of the commercial forest land is held in small tracts by private nonindustry owners.

These areas have often been subjected to a type of harvesting in which only the most marketable trees are harvested and in which little thought — and often no thought — is given to the future composition and condition of the timber stand. Even though the northern portion of the State is generally able to meet the demand for its major forest products, the groundwork for meeting the even greater demands of the future should be laid now.

This white pine stand was selectively logged 8 years ago.

MAINE FORESTRY DEPARTMENT PHOTO

As we have shown throughout this report, Maine's timber-resource situation cannot be described easily in broad terms. Differing stand conditions, ownership needs and desires, markets, and many other factors dictate that management planning is best carried out by technically trained personnel on a stand-by-stand basis. Therefore, we must consider the management of Maine's three most important forest types and the protection of Maine's forest from fire, insects, and diseases from an overall viewpoint. This section on forest management is far from complete. The reader who desires additional information about timber management is directed to the selected bibliography (page 36).

## MANAGEMENT OF EASTERN WHITE PINE

Eastern white pine—1.5 billion cubic feet of it—is one of the most important commercial timber species in Maine. Although the white pine forest type covers 11 percent of Maine's commercial forest land, white pine is also an important associate species in the maple-beech-birch and elm-ash-red maple types. White pine is also found in scattered patches throughout the spruce-fir region. White pine is one of the most versatile softwoods in North America.

Quality white pine is always in demand for use in a variety of products from lumber and furniture to patterns and millwork. But the problem in Maine, as in most of the white pine region, is to find quality material. Of the 4.6 billion board feet of white pine growing in Maine, about 88 percent is in grade 3 or poorer sawlogs. White pine grows well in Maine, but rarely does it produce quality timber without cultural treatment. White pine has two characteristics—susceptibility to white-pine weevil and the persistence of dead or dying branches—which are dominant considerations in managing the species. Both of these characteristics require considerable attention to prevent degrading the tree.

Perhaps the best place to begin a discussion of eastern white pine management is

with white pine's worst enemy, the white-pine weevil *(Pissodes strobi)*. This insect attacks and kills the terminal shoot of the tree. The resulting injury seldom causes the death of the tree, but the lateral branches compete for the position formerly held by the terminal shoot or leader. This inevitably produces a crook in the stem, which ultimately lowers log quality. The rapidity with which one lateral shoot asserts its dominance over the others determines the degree of the crook. In many cases, two laterals compete long enough to establish a forked tree. In addition to causing crook, weevil injury also causes a loss in stem length, affecting 2 or 3 years of growth. Lumber defects caused by weevil injury are: cross-grain, red rot, large branch knots, and loose knots. Weevil injury generally reduces board quality by one grade. Occasionally it may cause no degrade; yet in other cases it may cause a reduction of as much as three grades.

There are several techniques for controlling white-pine weevil damage. Chemical sprays can be used safely provided that precautions are observed with applications and dosage and that only properly registered insecticides are used. However, spraying from the ground is expensive and time-consuming, and aerial spraying has not proved successful.

Silvicultural controls of the weevil have been used, but with limited success. Where pine is growing as an understory of a hardwood stand it has been shown that weevil attack can be reduced by maintaining the hardwood overstory until the pine is about 20 feet tall. This method has the drawback that it tends to reduce height growth. However, if the overstory is composed of merchantable hardwoods, this drawback may be acceptable.

Where pine is growing in the open, the best approach seems to be to keep the stands densely stocked until the pine approaches 20 feet in height. This approach does not reduce the incidence of weevil attack; rather it minimizes the effect by forcing the stem to straighten out faster.

When all is said and done, there are some situations in which the forest manager will be forced to the decision of foregoing the expenditure of any major effort at weevil control. This would be true in stands that are beyond 8 feet in height or on poor sites, or in areas in which weevil damage is extremely intensive. The forest manager should weigh the costs of weevil control and its potential success against the possible return on the investment. This can be done only on a stand-by-stand, case-by-case basis.

Because of white pine's characteristic of retaining dead branches for as long as 50 years, successful management of white pine for quality timber must include a program of artificial pruning. Artificial pruning is a costly and time-consuming practice, but it pays off handsomely in quality lumber. In a study at the Pack Forest in New York State, 29 paired trees, one of which was pruned to a two-log height and the other left unpruned, were compared after 16 growing seasons. This comparison showed that, on average, the pruned trees yielded 40 percent select lumber while a comparable unpruned average tree yielded only 11 percent. More important, the retail lumber value of the unpruned tree was $32.43 on average, while the value of pruned trees was $36.98 each, a difference of $4.55 attributable to pruning alone. The cost of pruning was $.43 per tree. This study clearly demonstrates the value of pruning white pine.

Although white pine will grow just about anywhere in Maine where pine seed happens to land, not all areas are capable of producing quality stems. Sites that are very wet or very dry are not good sites. White pine seems to achieve its best development in Maine on light sandy soil with moderate soil moisture —as in southwestern Maine. In addition, the presence of quality pine, as previously described, is a good indication of a good pine site. Because producing quality pine is an expensive and time-consuming job, the forest manager should select the better sites and manage these intensively for quality production rather than attempt less-than-full treatment on all the stands available to him. There are no two ways about it: the production of quality white pine requires constant, long-term attention.

## MANAGEMENT OF NORTHERN HARDWOODS

The maple-beech-birch forest type, often called the northern hardwood type, is the most abundant hardwood forest type in Maine. Northern hardwoods cover about 29 percent of Maine's forest land; most of this is in the western portion of the State. It is the northern hardwood type that produces the

more valuable hardwood species such as sugar maple, yellow birch, paper birch, and white ash. This type also enhances the landscape by providing the vibrant autumn foliage and the striking contrast of scattered paper birch.

Most of Maine's northern hardwoods have been managed very little, if at all. Most have been harvested by high-grading methods, which removed only the high-value species or the best-quality trees. Because of these past practices, today's stands contain more beech, red maple, and similar low-value species than if they had been managed.

Northern hardwood stands in Maine, and elsewhere, can be divided into two groups—old-growth stands and second-growth stands. Old-growth stands are typically stands that were heavily harvested about the turn of the century. Since then they have either been left essentially untouched or they have been high-graded. They are typically uneven-aged, slow-growing stands with a wide distribution of diameter classes, and they have as much as one-third of their net volume in rough and rotten trees. Second-growth stands are more or less even-aged areas that have been truly clearcut or heavily high-graded. Most of these stands have a narrow range of diameters. In Maine many second-growth stands are approaching maturity; and because they are likely to be somewhat overstocked, growth rates are lower than they should be.

This then is a description of the present condition of Maine's northern hardwoods. What management practices might be employed to help realize the full potential of this type?

Generally speaking, northern hardwoods on the better sites can be managed to produce large specimens of the most valuable species. In old-growth stands it is often necessary to begin management with a salvage or improvement harvest that would remove 25 to 40 percent of the gross volume of the stand. This harvest would remove any tree that might die before the next harvest, low-quality or poor-vigor trees, less desirable species, multiple-stem trees, and any paper birch or aspen of merchantable size. In sections of the State that have active hardwood pulpwood markets, this harvest can be made profitable by the sale of pulpwood. The paper birch and other suitable species should be sold as turnery bolts if possible in order to realize a higher return.

The importance of frequent harvests or treatments in northern hardwoods, in which the selection system of silviculture is being employed, cannot be overemphasized. It is essential that some tree removal take place at least every 10 to 20 years to maintain optimum stocking for maximum growth of the higher-value trees. These repeated harvests should remove low-value species, rough and rotten trees, and sound mature trees of shorter-lived species such as aspen, birch, or ash. After each harvest the stand should contain, on the average, about 1,900 cubic feet per acre or 80 square feet of basal area.

The selection system favors the very tolerant species such as sugar maple, beech, hemlock, and red spruce. Where adequate markets for these species are available, or where aesthetic considerations are important, the selection system is the preferred method.

However, if birch or ash are present and adequate markets are available, some system of clearcutting, such as clearing small areas or strips, is preferred. Paper birch and white ash are both intolerant species, and both are high-value species. This means that, for these species to be present in the new stand, it is necessary to remove all the overstory competition and expose a mineral soil seedbed in which birch and ash seed can germinate and grow. Normally, small harvested areas should

A clearcut strip designed to regenerate white birch.

be about 1/3 to 2/3 acre in size, and strips should be 50 to 100 feet in width, with an adequate adjacent source of birch or ash seed. Also, it is important that birch should not be exposed on the north and east sides of clearings because this species is sensitive to sudden exposure and the higher soil temperatures that would occur in these locations. In both small and large clearcuttings, it is important to remove or kill all trees, merchantable or unmerchantable, over 2 inches d.b.h.

Considerable thought should be given to the location and size of cleared areas and to the geographical frequency of cleared areas where scenic considerations are important. The layman instinctively reacts negatively when he sees many areas or a large area on which every stem has been removed. Within view of roads where clearcutting is the most productive form of silviculture, signs or displays should be erected that explain the apparent devastation.

Second-growth stands should be managed in a manner similar to that described for old-growth stands where the tolerant species are desired. This requires frequent cleanings and thinnings to develop an uneven-aged stand structure. Where intolerant species are to be regenerated, the stand may be harvested in small clearings, strips, patches, or shelterwood harvests to encourage these species.

The key factors in managing northern hardwoods are to maintain optimum stand density, and thereby to maximize growth on the high-value trees; and to prevent the buildup of low-value species and rough and rotten trees in the stands. Many of the northern hardwood stands in Maine contain far more low-value or low-quality volume than would be acceptable under management. This need not be tolerated in locations with adequate markets for lower-quality material. Many stands could be commercially thinned and cleaned and sold for pulpwood. In many cases these intermediate operations would net the landowner some return on his investment while at the same time they would improve his woodland and increase the value of the remaining stems.

The northern hardwood type under management for timber production can be as pleasant and attractive as unmanaged stands. In fact, in most cases active management will improve appearance by replacing rough and rotten trees and less attractive low-value species with large sugar maples, beeches, or ashes.

## MANAGEMENT OF SPRUCE AND FIR

The spruce-fir forest type covers 7.9 million acres of Maine. Most of this area is in the northern half of the State, and much of it is in the more remote sections of the north country.

Spruce and balsam fir, more than any other species, were responsible for the rapid development of the woodpulp industry about the turn of the century. Today these species are still the mainstay of Maine's woodpulp industry. In 1970 about 1.9 million cords of spruce and balsam fir pulpwood were harvested from Maine's forest lands. Of this volume (more than all other species combined), 99 percent was converted into woodpulp in Maine mills.

Spruce lumber has always been an important product of Maine's forests. In all but 4 of the first 25 years of this century, spruce lumber production exceeded the production of white pine lumber. Over the years spruce has been the second most important softwood lumber species in Maine.

The spruce-fir type can be managed successfully under either the uneven-aged or even-aged management regimes. The system chosen will depend upon the objectives of the owner, the accessibility of the area, the labor supply, the available markets, and the site quality.

### UNEVEN-AGED MANAGEMENT

Uneven-aged management is best applied to areas with good sites that are accessible, and where the supply of both labor and markets is adequate. Stands that are managed under an uneven-aged system are usually managed for higher-value products such as sawlogs and veneer logs as well as for pulpwood and boltwood.

Spruce and fir are both shade-tolerant species, and they are capable of regenerating under shade. Because of their shade tolerance, the natural growth habit of undisturbed stands in the spruce-fir region is uneven-aged. However, many uneven-aged stands have been converted to even-aged stands because of such natural events as insect attack, severe windstorm, and fire.

In a system of uneven-aged management, stands are thinned and harvested at frequent intervals by single-tree or small-group selection. Uneven-aged management provides for the regeneration of stands through advance regeneration in the form of seedlings on the forest floor. Also, the frequency of harvests under uneven-aged silviculture allows the forest manager better control over the species mix of the stand, and to harvest the shorter-lived balsam fir before it dies. Insect or disease attack is less likely to wipe out stands with a mixture of species and age classes. From the aesthetic viewpoint, stands that are harvested frequently and lightly are generally considered more attractive by the public.

Forest management and harvesting is usually more complicated in uneven-aged stands than in even-aged stands because all operations must be conducted in a mixture of species and age classes. Harvesting operations are expensive because harvests are frequent and light and a large area must be covered to harvest a given volume. Also, it is difficult to utilize modern mechanical harvesting equipment because of the mixture of species and tree sizes. Damage to trees that are not intended for harvest is difficult to avoid, and windthrow of residual trees can also be a problem.

Stands must be scientifically harvested periodically in order to produce timber at their full potential. In this stand usable wood is being lost to insects and diseases as nature makes its own harvest.

The importance of periodic harvests in the uneven-aged system cannot be overemphasized. In accessible areas on better sites, the operating interval should be not more than 15 years; on less accessible or poorer sites, the interval can be extended to 20 or 25 years. Harvesting operations should remove not only the mature trees, but also poor-risk trees, poor-quality (due to vigor, form, or species), and trees that when removed will improve spacing. When only merchantable trees are removed, the productivity and quality of the stand will be lowered.

## EVEN-AGED MANAGEMENT

The development of highly mechanized harvesting systems has spurred an interest in even-aged management in the spruce-fir region. At one time even-aged management of spruce-fir was not looked upon as a satisfactory system. However, recent research has shown that it can be a satisfactory system of management for meeting particular objectives in many areas.

In even-aged management, harvesting is concentrated at the end of the rotation. Harvests may take the form of area, patch, or strip clearcuttings or shelterwood harvests. Under these methods the new stand is essentially even-aged. In managed even-aged stands in the spruce-fir region of Maine, one of the clearcutting methods of harvesting can usually be used because most spruce-fir stands have more than enough advance reproduction to adequately stock the new stand. In fact, it is often necessary to thin these new stands at some point during the rotation to maintain optimum stocking for maximum growth.

Like uneven-aged management, even-aged management has its advantages and disadvantages. Many advantages stem from its suitability for highly mechanized logging. With these harvesting systems individual trees do not need to be marked for cutting, and a large volume of wood can be harvested with less labor and at a lower per unit cost

than with other harvesting systems. Many mechanical harvesting systems permit the utilization of a greater portion of each tree harvested than do other systems.

Although even-aged stands are generally considered aesthetically displeasing by the public for a few years after harvesting, these same areas provide excellent wildlife habitat by increasing the amount of available food and cover for wildlife.

Because harvesting and cultural operations may not be as frequent as in uneven-aged management, forest road construction and maintenance is not as large a cost. In large clearcut areas a hot-dry microclimate can develop and reduce seed germination and seedling survival. Depending on the equipment used, some clearcut areas may have large accumulations of slash. These slash accumulations can smother seedlings and create a fire hazard. It should be pointed out, however, that in some mechanized harvesting systems the slash is scattered and presents less of a hazard than in conventional harvesting.

### A COMPROMISE

Many forest managers in the spruce-fir region have turned to diameter-limit harvesting as a compromise between the selection and clearcutting systems of harvesting. Under this method all trees over a specified minimum diameter are removed. Diameter limits range from 8 to 15 inches for the spruces and over 6 inches for balsam fir.

Though diameter-limit cutting keeps the cost of harvesting reasonably low and provides a form of partial harvesting that is conducive to future stand development, it has several shortcomings. Diameter-limit harvesting often removes large vigorous trees that might better be left to grow; and small, poor-risk and defective trees of all sizes may be left. In some areas harvesting by the diameter-limit method removes too many trees per acre, while in other areas not enough trees are removed. These drawbacks can be overcome to some extent by careful supervision of harvesting crews and by training crews to exercise judgment in the application of the diameter-limit guides.

This discussion of the principal methods of managing spruce and balsam fir shows that there are several silvicultural alternatives for harvesting and regenerating these species. The forest manager must constantly weigh many economic, biological, and social factors before he decides on the best management program for the area.

Spruce and fir are rarely found in pure stands. Usually they are found in mixture with such hardwood species as red maple and birch and with such softwoods as white pine, hemlock, and northern white-cedar. A major roadblock to more complete management and utilization of the spruce-fir forest is that markets for low-quality hardwoods are virtually nonexistent in many sections of northern Maine. Most of the pulpmills in Maine that can use hardwoods are in the southern half of the State. These mills have ample supplies of low-quality hardwoods within a reasonable hauling distance of the mill. Because of hauling costs, hardwoods from northern Maine cannot compete with this local wood. The establishment of a kraft process woodpulp mill in northern Maine that would depend primarily on the lower-quality hardwoods would be a significant step toward more complete management and utilization of the timber resources in the spruce-fir region.

## FOREST PROTECTION

An essential ingredient of successful management is the protection of the forest from fire, insects, and disease.

### FIRE PROTECTION

The Maine Forestry Department has the primary responsibility for protecting Maine's 17.7 million acres of forest land from fire. The magnitude of this job can be seen from the fact that in the fiscal year ended 30 June 1970, the Department spent $1,943,389 or 65 percent of its total expenditures for fire control *(7)*.

To provide adequate forest-fire control, the State has been divided into two different organizational districts, one covering the unorganized townships and one covering the organized towns. The Maine Forestry District (MFD), created in 1909, is composed primarily of the unorganized townships in the northern portion of the State. This district consists of an area of about 10 million acres of forest land. The owners of forest land in the Maine Forestry District provide three-fourths of the cost of fire protection through a tax on their property. The remaining fourth

comes from the Federal grant-in-aid programs. The Maine Forestry District is divided into three divisions—Northern, Eastern, and Western. Each division is headed by a District Ranger who is responsible for all fire control in his district.

The organized towns include 7 million acres divided into seven fire-control districts. Each district is further subdivided into units. Each district is headed by a District Ranger and each unit by a Unit Ranger. In the organized towns the town fire warden has the primary responsibility for fire control in his town. The duties of the State personnel are to maintain the watchman's towers and to assist the town fire warden in an advisory and training capacity. State personnel take over suppression operations only when requested by the town warden, or when several towns are involved. Funds for fire control in the organized towns come from legislative appropriations and Federal matching funds.

Through this dual system the State of Maine has compiled an impressive record of fire control. The following table shows that since 1910 the number of forest fires per year in Maine has generally increased, but the average size of the fires has declined from 205 acres during the 1910-19 decade to 8 acres during the 1960-69 decade.

| *Decade* | *Number of fires* | *Total acres burned* | *Average acres burned per fire* |
|---|---|---|---|
| 1910-1919 | 1,121 | 229,784 | 205 |
| 1920-1929 | 1,744 | 275,251 | 158 |
| 1930-1939 | 2,516 | 282,360 | 112 |
| 1940-1949 | 4,552 | 337,942 | 74 |
| 1950-1959 | 5,903 | 107,631 | 18 |
| 1960-1969 | 5,292 | 42,227 | 8 |

In 1970 there were 430 forest fires in Maine, and a total of 1,011 acres were burned. Of the 430 fires, all but 17 percent were caused by human carelessness or incendiarism. The most common cause of fire was debris-burning, followed by lightning. The cause of the fires in 1970 are shown as follows, and this distribution is typical for most years:

| *Cause* | *Number of fires* | *Percent of total* |
|---|---|---|
| Debris-burning | 99 | 23 |
| Lightning | 73 | 17 |
| Smoking | 60 | 14 |
| Incendiary | 52 | 12 |
| Children | 44 | 10 |
| Miscellaneous | 33 | 8 |
| Railroads | 27 | 6 |
| Camp fires | 26 | 6 |
| Machine use | 16 | 4 |
| Total | 430 | 100 |

## INSECT AND DISEASE PROTECTION

The Division of Entomology and Pathology of the Maine Forestry Department has overall responsibility for protection from and control of insect and disease pests of the State's forest and shade trees. To fulfill its responsibilities, the Division requires 16 percent of the Department's budget to mount a five-pronged attack on the State's insect-and-disease problems, consisting of:

1. Detection and assessment surveys
2. Research
3. Control measures, including: cultural, biological, chemical, and mechanical
4. Public education
5. Municipal shade-tree programs

Spruce budworm remains the State's No. 1 insect problem. This insect has caused extensive mortality of balsam fir and spruce in Maine since 1910. During the period 1910 to 1919, spruce budworm killed 27.5 million cords of spruce and fir. In recent years the destruction by budworms has been kept within bounds by aerial spraying.

Another constant problem is the white pine blister rust. To keep the rust under control, the State, in cooperation with the towns and the Federal Government, conducts surveys to detect Ribes plants, the intermediate host, and to eradicate them. White-pine weevil, an insect pest of white pine, has been discussed under white pine management. This pest also presents a constant threat to white pine.

Maine, like many of its sister states, is experiencing extensive losses of magnificent street and shade-tree elms from the Dutch elm disease. Since 1955 state technical and financial efforts, cooperatively with municipalities, have increased and have partially controlled the disease through sanitation programs. Successful containment of the disease is dependent upon the degree of commitment by each municipality.

The four insect and disease problems discussed above are only a fraction of the total list of insects and diseases that require control in Maine. To discuss each of them would fill many pages.

# Appendix

## DEFINITION OF TERMS

### Land Area Classes

*Land area.*—(a) Bureau of the Census. The area of dry land and land that is temporarily or partly covered by water, such as marshes, swamps, and river flood plains; streams, sloughs, estuaries, and canals that are less than ⅛ statute mile in width; and lakes, reservoirs, and ponds that are less than 40 acres in area. (b) Forest Survey. The same as the Bureau of the Census, except that the minimum width of streams, etc., is 120 feet, and the minimum size of lakes, etc., is 1 acre.

*Forest land.*—Land that is at least 16.7 percent stocked (contains at least 7.5 square feet of basal area) by forest trees of any size, or that formerly had such tree cover and is not currently developed for nonforest use. (Forest trees are woody plants that have a well-developed stem and usually are more than 12 feet in height at maturity.) The minimum area for classification of forest land is 1 acre.

*Commercial forest land.*—Forest land that is producing or capable of producing crops of industrial wood (more than 20 cubic feet per acre per year) and is not withdrawn from timber utilization. (Industrial wood: all roundwood products except fuelwood.)

*Noncommercial forest land.*—Forest land that is incapable of yielding timber crops because of adverse site conditions (unproductive forest land), and productive forest land that is withdrawn from commercial timber use (productive-reserved forest land).

*Productive-reserved forest land.*—Forest land that is sufficiently productive to qualify as commercial forest land, but is withdrawn from timber utilization through statute, administrative designation, or exclusive use for Christmas-tree production.

*Unproductive forest land.*—Forest land that is incapable of producing 20 cubic feet per acre of industrial wood under natural conditions, because of adverse site conditions.

*Nonforest land.*—Land that has never supported forests, and land formerly forested but now in nonforest use such as for crops, improved pasture, residential areas, and the like.

*Unorganized territory or towns (Maine).*—An area that does not have any form of organized local government and still is a minor civil division.

### Ownership Classes

*National Forest.*—Federal lands that have been legally designated as National Forests or purchase units and other lands that are under the administration of the Forest Service.

*Other Federal.*—Lands (other than National Forests) that are administered by Federal agencies.

*State.*—Lands that are owned by the State of Maine or leased to the State for 50 years or more.

*County and municipal.*—Lands that are owned by counties and local public agencies or municipalities or leased to them for 50 years or more.

*Forest industry.*—Lands that are owned by companies or individuals operating wood-using plants.

*Farmer-owned.*—Lands that are owned by farm operators, whether part of the farmstead or not. Excludes land leased by farm operators from nonfarm owners.

*Miscellaneous private.* — Privately owned lands other than forest-industry and farmer-owned lands.

### Stand-size Classes

*Stand.*—A growth of trees (see definitions under "Tree Classes") on a minimum of 1 acre of forest land that is at least 16.7 percent stocked by forest trees of any size.

*Sawtimber stands.*—Stands that are at least 16.7 percent stocked with growing-stock trees, with half or more of total stocking in sawtimber or poletimber trees, and with sawtimber stocking at least equal to poletimber stocking.

*Poletimber stands.*—Stands that are at least 16.7 percent stocked with growing-stock trees of which half or more of this stocking is in poletimber and/or sawtimber trees and with poletimber stocking exceeding that of sawtimber.

*Sapling-seedling stands.*—Stands that are at least 16.7 percent stocked with growing-stock trees of which more than half of the stocking is saplings and/or seedlings.

*Nonstocked areas.*—Commercial forest land that is less than 16.7 percent stocked with growing-stock trees.

### Stocking Classes

*Stocking.*—The degree of occupancy of land by trees, measured in terms of basal area of trees in a stand compared to the basal area of trees required to utilize fully the growth potential of the land. The actual stocking at a point was evaluated against a standard of 75 square feet of basal area per acre (see definition of basal area under "Tree Measurement and Volume"). The stocking percentage for a sample plot is derived from the stocking for each of 10 points. Three categories of stocking are used:

*All live trees.*—These are used in the classification of forest land and forest types.

*Growing-stock trees.*—These are used in the classification of stand-size classes.

*Desirable trees.*—These are used in the classification of area-condition classes.

The degree of plot stocking is viewed as a range of values rather than single points. A fully stocked stand lies within the range of 100 to 133 percent of the basal-area standard. An overstocked stand contains more than 133 percent. The range for medium stocking is 60 to 100 percent and for poor stocking is 16.7 to 60 percent of the basal-area standard. Forest land with less than 16.7 percent of the basal-area standard is classed as nonstocked.

## Tree Classes

*Forest trees.*—Woody plants that have a well-developed stem and usually are more than 12 feet in height at maturity.

*Commercial species.*—Tree species that are presently or prospectively suitable for industrial wood products. Excludes species of typically small size, poor form, or inferior quality, such as hawthorn and sumac.

*Growing-stock trees.* — Live trees of commercial species that are classified as sawtimber, poletimber, saplings, and seedlings; that is, all live trees of commercial species except rough and rotten trees. (See definitions under "Class of Timber.")

*Acceptable trees.*—Growing-stock trees of commercial species that meet specified standards of size and quality, but do not qualify as desirable trees.

*Desirable trees.*—Growing-stock trees of commercial species, (a) that have no serious quality defects that limit present or prospective use for timber products, (b) that are of relatively high vigor, and (c) that contain no pathogens that may result in death or serious deterioration before rotation age.

*Rotten trees.*—Live trees of commercial species that do not contain at least one 12-foot sawlog or two noncontiguous sawlogs, each 8 feet or longer, now or prospectively, and do not meet regional specifications for freedom from defect primarily because of rot; that is, when more than 50 percent of the cull volume in a tree is rotten.

*Rough trees.*—(a) The same as above, except that rough trees do not meet regional specifications for freedom from defect primarily because of roughness or poor form, and (b) all live trees that are of noncommercial species.

## Site-Quality Classes

*Site class.*—A classification of forest land in terms of inherent capacity to grow crops of industrial wood. Classifications are based upon the mean annual growth of growing stock attainable in fully stocked natural stands at culmination of mean annual growth.

## Forest Types

*Forest type.*—A classification of forest land based upon the species forming a plurality of live-tree stocking. The many local forest types in Maine were combined into the following major forest types:

*White pine—red pine—hemlock.*—Forests in which eastern white pine, red pine, or hemlock, singly or in combination, make up a plurality of the stocking. (Common associates include aspen, birch, and maple.)

*Spruce—fir.*—Forests in which spruce or balsam fir, singly or in combination, make up a plurality of the stocking. Cedar swamps are also in this type. (Common associates include white-cedar, tamarack, maple, birch, and hemlock.)

*Oak and Oak-pine.*—(a) *Oak:* Forests in which oaks or hickory, singly or in combination, make up a plurality of the stocking, except where pines make up 25 to 50 percent, in which case the stand would be classified oak-pine. Hickory is seldom present in Maine. (Common associates include elm and maple.) (b) *Oak-pine:* Forests in which hardwoods make up a plurality of the stocking, but in which pines make up 25 to 50 percent of the stocking.

*Elm—ash—red maple.*—Forests in which elm, ash, or red maple, singly or in combination, make up a plurality of the stocking. (Common associates include beech and basswood.)

*Maple—beech—birch.* — Forests in which sugar maple beech, or yellow birch, singly or in combination, make up a plurality of the stocking. (Common associates include hemlock, elm, basswood, and white pine.)

*Aspen—birch.*—Forests in which aspen, balsam poplar, paper birch, or gray birch, singly or in combination, make up a plurality of the stocking. (Common associates include maple and balsam fir.)

## Class of Timber

*Softwoods.* — Coniferous trees that are usually evergreen, having needles or scalelike leaves.

*Hardwoods.*—Dicotyledonous trees that are usually broad-leaved and deciduous.

*Sawtimber trees.*—Live trees of commercial species, (a) that are of the following minimum diameters at breast height—softwoods 9.0 inches and hardwoods 11.0 inches, and (b) that contain at least one 12-foot merchantable sawlog and meet regional specifications for freedom from defect.

*Poletimber trees.*—Live trees of commercial species that meet regional specifications of soundness and form, and are at least 5.0 inches in d.b.h. but are smaller than sawtimber size.

*Saplings.*—Live trees of commercial species that are 1.0 to 5.0 inches in diameter at breast height and of good form and vigor.

*Seedlings.*—Live trees of commercial species that are less than 1.0 inches in diameter at breast height and are expected to survive.

*Rough and rotten trees.*—See definitions under "Tree Classes."

## Timber Measurement and Volume

*Basal area.*—The area in square feet of the cross section at breast height of a single tree, or of all the trees in a stand, usually expressed as square feet of basal area per acre.

*Board foot.*—A unit of lumber measurement 1 foot long, 1 foot wide, and 1 inch thick, or its equivalent. By forest-survey convention, softwoods less than 9.0 inches d.b.h. and hardwoods less than 11.0 inches d.b.h. do not contain board-foot volume.

*Diameter at breast height (d.b.h.).*—The diameter outside bark of a standing tree measured at 4½ feet above the ground.

*Growing-stock volume.*—Net volume, in cubic feet, of live growing-stock trees that are 5.0 inches d.b.h. and over, from a 1-foot stump to a minimum 4.0-inch top diameter outside bark of the central stem,

or to the point where the central stem breaks into limbs. Net volume equals gross volume less deduction for rot.

*International ¼-inch rule.*—A log rule, or formula, for estimating the board-foot volume of logs. Stated mathematically, the formula is $[\{D^2 \times 0.22\} - 0.71\ D] \times 0.904762$ for 4-foot sections, where D = the diameter inside bark at the small end of the 4-foot section. The International ¼-inch rule is used as the USDA Forest Service standard log rule in the northeastern United States.

*Standard cord.*—A unit of measure for stacked bolts of wood, encompassing 128 cubic feet of wood, bark, and air space. Cord estimates can be derived from cubic-foot estimates of growing stock by applying an average factor of 80 cubic feet of wood (inside bark) per rough cord; the cubic-foot estimates of volume suitable for pulpwood in Maine can be converted to cords by dividing by an average factor of 85 cubic feet of wood per rough cord in lieu of any other converting factors.

*Sawtimber volume.*—Net volume in board feet, International ¼-inch rule, of merchantable sawlogs in live sawtimber trees. Net volume equals gross volume less deductions for rot, sweep, and other defects that affect use for lumber.

*Sawlog.*—A log that meets minimum standards of diameter, length, and defect, including logs at least 8 feet long, and with a minimum diameter inside bark of 6 inches for softwoods and 8 inches for hardwoods. (See specifications under "Log Grade Classification.")

*Sawlog portion.*—That part of the bole of a sawtimber tree between the stump and the sawlog top (merchantable height).

*Sawlog top.*—The point on the bole of a sawtimber tree above which a sawlog cannot be produced. The minimum sawlog top is 7.0 inches d.o.b. for softwoods and 9.0 inches d.o.b. for hardwoods.

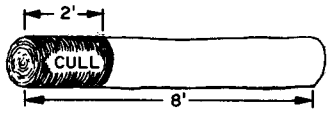
*Upper-stem portion.*—That part of the main stem or fork of a sawtimber tree above the sawlog top to a diameter of 4.0 inches outside bark or to the point where the main stem or fork breaks into limbs.

## Log Grade Classification

Log grades are a classification of logs based on external characteristics as indicators of quality or value. The log-grade standards and grading systems for softwood and hardwood species used in this forest survey of Maine are shown in the following specifications:

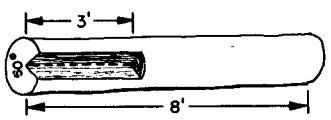
### METHODS USED TO DETERMINE SCALING DEDUCTION

*(Examples based on an 8-foot log with 20-inch scaling diameter)*



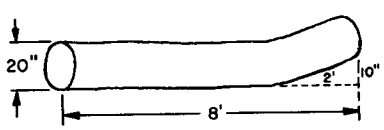
If section of bole is affected, deduct percent of log length affected.

Example $\frac{2}{8}$ = 25 percent cull



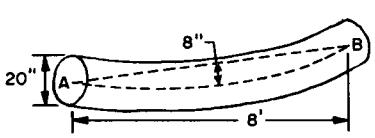
If sector is affected, multiply percent of circle times percent of length.

Example: $\frac{60°}{360°} \times \frac{3}{8}$ = 6 percent cull



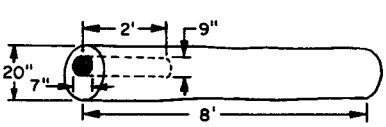
For a crook, multiply proportion of diameter displaced times proportion of log length affected by crook.*

Example: $\frac{10}{20} \times \frac{2}{8}$ = 12 percent board-foot cull



For a sweep, determine sweep departure and subtract 1 inch for 8-foot logs or 2 inches for 16-foot logs. Divide by log diameter.

Example: $\frac{8 - 1}{20}$ = 35 percent board-foot cull**



For interior cull, square out interior cull as a percent of total volume of the section. For board-foot cull, add 1 inch to width and to thickness; for cubic-foot cull, use actual dimensions of rot. For board-foot cull divide width and thickness by the scaling diameter (average d.i.b., small end) minus 1; for cubic-foot cull, divide by scaling diameter. Multiply fractions by percent of log affected.

Example: $\frac{8 \times 10}{20\text{-}1} \times \frac{2}{8}$ = 6 percent cubic-foot cull

* No reduction of cubic-foot volume will be made.

** If a straight line between A and B falls outside the bark, the affected section is over 50 percent cull in board feet.

## WHITE PINE LOG GRADES

*(Unpublished trial specifications, revised 1963)*

| Log grade | Minimum size | | Defect allowance | | Maximum weevil injury | Allowable knot size (inches) on 3 best faces or minimum clearness on 4 faces |
|---|---|---|---|---|---|---|
| | Diameter | Length[1] | Sweep or crook | Total cull including sweep | | |
| | *Inches* | *Feet* | *Percent* | *Percent* | *Number* | *Inches* |
| No. 1 | 12 & 13 | 8–16 | 20 | 50 | 0 | 4 faces free of knots ½″ or larger full length of log. |
| | 14+ | 10–16 | 20 | 50 | 0 | 2 faces free of knots ½″ or larger full length of log, or 4 faces free of knots ½″ or larger 50 percent length of log (6′ minimum length)[2]. |
| No. 2 | 6+ | 8–16 | 30 | 50 | 0 | Sound red knots $\leqq$[3] D/6 and no larger than 3″.<br>Black knots:<br>Butt logs $\leqq$ D/12 and no larger than 1½″.<br>Upper logs $\leqq$ D/10 and no larger than 1½″.<br>or<br>4 faces free of knots ½″ or larger 50 percent length of log. |
| No. 3 | 6+ | 8–16 | 40 | 50 | 8′ logs: 1 weevil<br>10′+ logs: 2 weevils | Sound red knots $\leqq$ D/3 and no larger than 5″.<br>Black knots $\leqq$ D/6 and no larger than 2½″. |
| No. 4 | 6+ | 8–16 | 50 | 50 | No limit | No limit. |

[1] Plus trim.

[2] If the sum of the diameters of sound red knots plus 2X (sum of the diameters of dead or black knots) in inches is $\leqq$ ½ the diameter of the log (in inches).

[3] $\leqq$ means equal to or less than.

## SPRUCE, FIR, HEMLOCK, TAMARACK, AND CEDAR LOG GRADE

*(Minimum merchantability specifications)*

| Log grade | Minimum size | | Defect allowance | | Other requirements |
|---|---|---|---|---|---|
| | Diameter[1] | Length[2] | Sweep or crook | Total deduction | |
| | *Inches* | *Feet* | *Percent* | *Percent* | |
| 1 | 10–12 | 8–16 in 2-foot multiples | 25 | 50 | Sound knots not over 2 inches in diameter permitted. Shake permitted up to 20 percent of gross scale if not combined with other serious defects. |
| | 13+ | 8–16 in 2-foot multiples | 25 | 50 | Sound knots not over 3 inches in diameter permitted. Shake permitted up to 20 percent of gross scale if not combined with other serious defects. |

[1] At small end of log.

[2] Without trim.

## HARDWOOD FACTORY LUMBER LOG-GRADE SPECIFICATIONS

*(From U.S. Forest Products Laboratory Report D 1737)*

| GRADE FACTORS* | | SPECIFICATIONS | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | Log Grade 1 | | | Log Grade 2 | | | | Log Grade 3 |
| Position in tree | | Butts only | Butts & uppers | | Butts & uppers | | | | Butts & uppers |
| Minimum diameter (inches) | | 13–15[1] | 16–19 | 20+ | 11[2] | | 12+ | | 8+ |
| Minimum length (feet) | | 10+ | 10+ | 10+ | 10+ | 8–9 | 10–11 | 12+ | 8+ |
| Clear cuttings** on each of the 3 best faces | Min. length (ft.) | 7 | 5 | 3 | 3 | 3 | 3 | 3 | 2 |
| | Max. number | 2 | 2 | 2 | 2 | 2 | 2 | 3 | — |
| | Min. yield in face length | 5/6 | 5/6 | 5/6 | 2/3 | 3/4 | 2/3 | 2/3 | 1/2 |
| Max. sweep and crook allowance (percent of gross volume) | | 15 | | | 30 | | | | 50 |
| Max. cull and sweep allowance (percent of gross volume) | | 40[3] | | | 50[4] | | | | 50 |

* End defects, although not visible in standing trees, are important in grading cut logs. Instructions for dealing with this factor are contained in Forest Prod. Lab. Rpt. D 1737.

** A clear cutting is a portion of a face free of defects, extending the width of the face. A face is one-fourth the surface of the log as divided lengthwise.

[1] Ash and basswood butts can be 12 inches if otherwise meeting requirements for small No. 1's.

[2] 10-inch logs of all species can be No. 2 if otherwise meeting requirements for small No. 1's.

[3] Otherwise No. 1 logs with 41-50 percent cull can be No. 2.

[4] Otherwise No. 2 logs with 51-60 percent cull can be No. 3.

Source: A Guide to Hardwood Log Grading (pg 11), NE. Forest Exp. Sta., Upper Darby, Pa. 1965.

## HARDWOOD CONSTRUCTION LOG SPECIFICATIONS

| GRADE FACTORS | | SPECIFICATIONS |
|---|---|---|
| Position in tree | | Butts and uppers |
| Scaling diameter (inches) | | 8+ |
| Length, without trim (feet) | | 8+ |
| Clear cuttings | | No requirements: not graded on cutting basis. |
| Max. sweep allowance | | One-fourth d.i.b. of small end for half logs, and one-half d.i.b. for logs 16 feet long. |
| Sound surface defects permitted | Single knots | Any number, if none has an average collar* diameter that is more than one-third of log diameter at point of occurrence. |
| | Whorled knots | Any number, provided the sum of the collar diameters does not exceed one-third the log diameter at point of occurrence. |
| | Holes | Any number not exceeding knot specifications if they do not extend more than 3 inches into the contained tie or timber. |
| Unsound surface defects permitted** | | Any number and size if they do not extend into contained tie or timber. If they extend into contained tie or timber, they shall not exceed size, number, and depth of limits for sound defects. |

* Knot collar is the average of the vertical and horizontal diameters of the limb or knot swelling as measured flush with the surface of the log.

** Interior defects are not visible in standing trees. They are considered in grading cut logs. No interior defects are permitted except one shake not more than one-third the width of the contained tie or timber, and one split not more than 5 inches long.

Source: A Guide to Hardwood Log Grading, (pg. 28), NE. Forest Exp. Sta., Upper Darby, Pa. 1965.

### Net Annual Growth and Timber Removals

*Average annual net growth of growing stock.*—The change (resulting from natural causes) in volume of sound wood in sawtimber and poletimber trees during the period between surveys, divided by the length of the period. (Components of annual net growth of growing stock include the increment in net volume of trees present at the beginning of the period and surviving to its end, plus net volume of trees reaching poletimber size during the period, minus the net volume of trees that died during the period, minus the net volume of trees that became rough or rotten trees during the period, cull increment.)

*Average annual ingrowth of growing stock.*—The net cubic-foot volume of trees now classed as growing stock that were less than 5.0 inches d.b.h. on the initial survey, divided by the length of the period between surveys.

*Average annual mortality of growing stock.*—The net cubic-foot volume removed from the growing stock because of death from natural causes during the period between surveys, divided by the length of the period between surveys.

*Average annual growing-stock removals.*—The net cubic-foot volume of growing-stock trees harvested or killed in logging, cultural operations such as timber-stand improvement, land-clearing, or changes in land use during the period between surveys, converted to an annual basis.

*Average annual net growth of sawtimber.*—The change (resulting from natural causes) in net board-foot volume of sawtimber during the period between surveys, divided by the length of the period. (Components of annual net growth of sawtimber include the increment in net volume of sawtimber trees present at the beginning of the period and surviving to its end, plus the net volume of trees reaching sawtimber size during the period, minus the net volume of sawtimber trees that died during the period, minus the net volume of sawtimber trees that became rough or rotten during the period between surveys, cull increment.)

*Average annual ingrowth of sawtimber.*—The net board-foot volume of trees now classed as sawtimber that were not tallied as such on the initial survey, divided by the length of the period between surveys.

*Average annual mortality of sawtimber.*—The net board-foot volume removed from live sawtimber by death from natural causes during the period between surveys, divided by the length of the period between surveys.

*Average annual sawtimber removals.*—The net board-foot volume of sawtimber trees harvested or killed in logging, cultural operations such as timber-stand improvement, land-clearing, or changes in land use during the period between surveys, converted to an annual basis.

*Cull increment.*—The net volume of growing-stock trees on the initial inventory that became rough or rotten trees in the second inventory.

*Logging residues.*—The unused growing-stock volume of trees cut for products and the total growing-stock volume of trees destroyed in the course of logging but not removed for products.

*Other removals.*—The growing-stock volume of trees that were removed from the inventory and not used for products, by cultural operations (i.e., weeding, thinning, etc.), land-clearing, and reclassification of some commercial forest land as noncommercial forest land.

*Plant byproducts.*—Wood products, such as slabs, edgings, and veneer cores, that are obtained incidental to the production of timber products and are utilized in the manufacture of other timber products. (Bark is not included.)

*Plant residues.*—Wood material produced incidental to the production of timber products but not utilized.

*Roundwood products.*—Logs, bolts, or other round sections cut from growing stock or non-growing stock for industrial or nonindustrial uses.

*Timber products.*—Roundwood products and plant byproducts from all sources.

*Timber removals.*—The growing-stock volume of trees removed from the inventory for roundwood products, plus logging residues and other removals.

*Annual net growth trend-level.*—The estimated growth of growing stock or sawtimber for a specific year that is consistent with the average annual growth during the period between surveys and with the current inventory. (1970 for Maine.)

*Annual removals trend-level.*—The estimated removals of growing stock or sawtimber for a specific year that is consistent with the trend of removals during the period between surveys and with the current inventory. (1970 for Maine.)

## FOREST-SURVEY METHODS

The Northeastern Forest Experiment Station's Forest Survey project used the sampling-with-partial replacement (SPR) design in the re-inventory of Maine's timber resource. With this design, estimates of forest area and timber volume were made by combining a subsample of remeasured plots, a regression updating of the initial inventory, and a new independent photo and ground-plot inventory. Thus the SPR design, by combining two independent estimates of the inventory, yields a better estimate of the timber resource at a given cost.

One estimate is based on the updating of the initial survey (1959). This required the remeasurement of a subsample of the initial inventory ground plots. With the area-change and current-volume estimates obtained from the remeasured sample plots, regression techniques were used to update all the initial ground and photo plots to obtain an independent estimate of current timber volume and forest area.

The second estimate is also based on a large photo-plot sample with a subsample of ground plots. For the second estimate the most recent aerial photography coverage of Maine was used. Photo plots were pinpointed on each photograph to provide a uniformly distributed sample of the area. Each photo plot was examined stereoscopically and classified as either forest or nonforest land. Those

classified as forest land were further stratified into cubic-foot-volume-per-acre classes. A subsample of these photo plots, which was selected to be proportional to the area in a photo class, was measured on the ground. From this ground measurement, estimates of the mean and variance of each photo class were obtained. These means were expanded by photo-strata areas to yield a second independent estimate of forest area and timber volume.

The final estimates of current forest area and timber volume were developed by combining these two independent estimates. The combination process consisted of weighting each estimate by the reciprocal of its variance and then adding them. The associated sampling error for this new estimate was also obtained. These combined totals were partitioned into the various categories of area and volume (e.g., volume by species and d.b.h. class) using the data obtained from the new ground-plot sample.

In addition to estimating current timber volume and forest area, the forest survey of Maine was designed to obtain an estimate of the components of average annual change during the period between the initial and the current inventories. The parameters of interest include area change from forest to nonforest and vice versa, timber growth, timber removals, and timber mortality. All this information was obtained from the remeasured plots. The timber-change parameters were obtained by a tree-by-tree reconciliation of each remeasured plot. The reconciliation code for each remeasured tree was used to make estimates of the parameters of change, by species. The estimates of change were expressed as an average annual figure by dividing the total for the period by the number of years between measurements. These estimates were then used to compute the annual net growth, mortality, and removals for 1970.

## Remeasured-Plot Phase

The initial forest inventory of Maine consisted of a large photo-plot sample plus a ground measurement of a subsample of these photo plots. (At the initial survey occasion, the ground plots were selected according to optimum allocation for volume estimation.) The photo plots were stratified according to land use as forest or nonforest. The forest plots were further classified into volume classes. A total of 2,267 ground plots were measured by field crews during this first inventory. These ground samples were 1/5-acre circular plots.

At this second measurement occasion, a sample of 902 of the initial ground plots (including 62 nonforest plots)—selected randomly within each initial photo-plot class—was revisited. These remeasured plots were distributed within the nine geographic units of Maine as follows:

| | |
|---|---|
| Washington County | 60 |
| Aroostook County | 211 |
| Penobscot County | 98 |
| Hancock County | 61 |
| Piscataquis County | 130 |
| Capitol Region | 55 |
| Somerset County | 116 |
| Casco Bay Region | 68 |
| Western Maine | 103 |

The plot center was relocated for each remeasured plot. On those plots that were forested, all the trees on the 1/5-acre were tallied. The new tally was reconciled with the initial tally to account for every tree at both occasions.

## New Ground-Plot Phase

The source of the new independent estimates of volume and forest area was a new photo stratification with a subsample of ground measurements. The photo sample of Maine consisted of about 36,000 photo points on the latest available aerial photography. A subset of 1,587 of these photo plots, including 159 nonforest plots, was located on the ground. Land use was verified and tree-measurement data were recorded for the 1,428 forest plots. Unlike the initial inventory, in which fixed-radius 1/5-acre plots were tallied, the new ground plots consisted of a cluster of 10 prism points systematically covering approximately 1 acre. At each point, trees were selected for tally by using a prism with a basal-area factor of 37.5. Area-attribute data were also tallied at each of the 10 points.

The new ground plots in Maine were distributed within the geographic strata as follows:

| | |
|---|---|
| Washington County | 157 |
| Aroostook County | 360 |
| Penobscot County | 172 |
| Hancock County | 76 |
| Piscataquis County | 187 |
| Capitol Region | 118 |
| Somerset County | 198 |
| Casco Bay Region | 131 |
| Western Maine | 188 |

## Data Processing

Field tally data consisting of plot and individual-tree information were processed and compiled into various tables, using FINSYS—Forest Inventory System — on modern, large-capacity, high-speed computers.

FINSYS is a data-processing system consisting primarily of a series of computer programs that was developed by the Northeastern Forest Experiment Station to process and compile a large volume of forest-inventory data. The system consists of an editing subsystem that edits field tally data for errors; a table-compiling subsystem that compiles tables from edited field data; and, finally, an output subsystem that expands the plot data to geographic unit or statewide estimates and prints the final tables.

FINSYS was described in a series of research papers by R. W. Wilson and R. C. Peters in 1967: *The Northeastern Forest Inventory Data Processing System,* USDA Forest Service Research Papers NE-61 and NE-70 to 80.

Before modern computers came into use, the compiling of forest-inventory data was a major bottleneck in forest-inventory work. Using FINSYS, it is possible, as in the case of the resurvey of Maine, to have preliminary estimates available for geographic units within 6 months after the last plot is taken. To process and compile a geographic

unit, from key-punching to the output of tables, requires about 2½ months of elapsed time and about 2½ hours of computer time.

FINSYS has several features that make it unique. One of these is the ability not only to calculate inventory estimates but also to calculate the variance and sampling error for each estimate. This feature provides the user with a measure of the reliability of each statistic and the ability to determine the reliability of a new estimate based upon a data combination he may make.

Another feature of FINSYS is its flexibility. The system is not restricted to the Northeastern forest survey, but can be used for any large-scale forest inventory. Also, the system does not produce a standard set of tables. The individual user specifies the tables to be developed according to his particular need. Thus, at any stage in the data-processing phase or even at a later date, a specific table can be developed with minimum effort.

The data-processing of the resurvey of Maine entailed the preparation and processing of approximately 100,000 data cards. The data from these cards were used to compile more than 50 different tables for each of the nine geographic units in Maine.

### County Data

Many users of forest-survey data have shown a need for county information. To provide such information within the framework of the survey design, tables for counties where more than one county makes up a geographic stratum have been developed, based on a survey-unit partitioning technique.

First the survey-unit means and variances for the various photo-plot strata were applied to the photo-plot data for each county within the survey unit. This yielded an estimate of total volume or total commercial forest-land area for each county. Next, the data from all the new ground plots in the unit were used to partition the county totals into their various components. For example, if a table of cubic-foot volume by softwoods and hardwoods is to be made for a county, the estimate of total cubic-foot volume for that county is partitioned into softwood and hardwood totals according to the proportion of softwoods and hardwoods for all new forest-survey ground plots within the unit.

In those units that contain only one county, the county is synonymous with the geographical unit.

### Comparisons Between Inventories

After inventories have been completed for several points in time, it is desirable to evaluate the trends between the several inventories and to make comparisons. A comparison of the 1970-71 and the 1958-59 forest-survey estimates of volume, growth, removals, and mortality was made for Maine. A computer program, TRAS (Timber Resource Analysis System), was used.

Since the survey-unit boundaries were different at the first occasion, no direct comparisons of published data can be made between units. Present plans call for the same units to be used for the third inventory as were used for the second inventory so comparisons between units will be possible at that time. The procedure for obtaining county data (see "Forest Survey Methods") was different on the two surveys, so comparisons of area and volume for a county are subject to procedural differences in the estimates as well as to sampling errors.

Because of changes in procedures and in definitions it was necessary to adjust the 1959 inventory-volume estimate to what it would have been had the 1968-70 procedures and definitions been used in 1959. This process involved several calculations and adjustments in the 1959 inventory in order to make it comparable with the 1971 inventory. One important step in this process was to recalculate the 1959 inventory volume, using the average net volume per tree from the resurvey. To do this, the average net volume per tree developed from the resurvey for each 2-inch diameter class was multiplied by the number of trees in each 2-inch diameter class from the 1959 inventory. These calculations resulted in an inventory estimate for 1959 adjusted to 1968-70 standards. These adjusted 1959 volume estimates for Maine are:

- For softwood growing-stock volume, 6.6 percent greater than was reported.
- For hardwood growing stock volume, both the adjusted and reported estimates are the same.
- For softwood sawtimber volume, 5.6 percent lower than reported.
- And for hardwood sawtimber volume, 2.3 percent lower than reported.

It is these adjusted 1959 estimates, not the volume estimates published in the report of the 1959 survey, that are the basis for comparisons between surveys shown in this report.

## RELIABILITY OF THE ESTIMATES

The forest-area and timber-volume data presented in this report were based upon a carefully designed sample of forest conditions throughout Maine. However, since neither every acre nor every tree in the State was measured, the data presented in this report are estimates. A measure of the reliability of these estimates is given by a sampling error. An associated sampling error was calculated for each estimate in this report. These appear in the data tables.

Briefly, this is how the sampling error indicates the reliability of an estimate. Our estimate of the total growing-stock volume in Maine—21,253 million cubic feet—has an associated sampling error of 0.9 percent (191 million cubic feet). This means that our best estimate of the total growing-stock volume in Maine in 1971 is 21,253 million cubic feet. If there are no errors in procedure, the odds are 2 to 1 that, if we repeated the survey in the same way, the resulting estimate of growing-stock volume would be between 21,062 million and 21,444 million cubic feet (21,253 ± 191). Similarly, the odds are 19 to 1 that it would be within ± 382 million cubic feet and 300 to 1 that it would be within ± 573 million cubic feet.

The computed sampling error is not a complete measure of reliability. There are other sources of error that this term does not include. There could be imperfections in volume tables and equations and errors in field measurement. Procedural errors were kept to a minimum by careful training of all personnel, frequent inspection of field work, and application of the most reliable survey methods.

Computed sampling errors for the totals shown in the statistical tables are:

| | *Sampling error (percent)* |
|---|---|
| Commercial forest area: 16.9 million acres | 0.4 |
| Growing-stock volume: 21.3 billion cubic feet | .9 |
| Sawtimber volume: 34.5 billion board feet | 1.6 |
| Annual net growth: 711 million cubic feet | 4.0 |
| Annual removals: 409 million cubic feet | 12.0 |

## COMMON COMMERCIAL SPECIES OF MAINE

Names are according to Elbert L. Little, Jr.: *Check list of native and naturalized trees of the United States (including Alaska)*. U. S. Dep. Agr. Handbook 41, 472 pp., 1953.

### Softwoods

| | |
|---|---|
| Eastern white pine | *Pinus strobus* |
| Red pine (Norway) | *P. resinosa* |
| Pitch pine | *P. rigida* |
| Norway spruce | *Picea abies* |
| White spruce | *P. glauca* |
| Black spruce | *P. mariana* |
| Red spruce | *P. rubens* |
| Balsam fir | *Abies balsamea* |
| Eastern hemlock | *Tsuga canadensis* |
| Atlantic white-cedar | *Chamaecyparis thyoides* |
| Eastern redcedar | *Juniperus virginiana* |
| Tamarack | *Larix laricina* |
| Northern white-cedar | *Thuja occidentalis* |

### Hardwoods

| | |
|---|---|
| Sugar maple | *Acer saccharum* |
| Red maple | *A. rubrum* |
| Silver maple | *A. saccharinum* |
| American beech | *Fagus grandifolia* |
| White ash | *Fraxinus americana* |
| Black ash (brown) | *F. nigra* |
| Green ash (red) | *F. pennsylvanica* |
| Yellow birch | *Betula alleghaniensis* |
| Sweet birch (black) | *B. lenta* |
| Paper birch (white) | *B. papyrifera* |
| Gray birch | *B. populifolia* |
| Quaking aspen (Popple) | *Populus tremuloides* |
| Bigtooth aspen (Popple) | *P. grandidentata* |
| Balsam poplar | *P. balsamifera* |
| White oak | *Quercus alba* |
| Northern red oak | *Q. rubra* |
| Black oak | *Q. velutina* |
| Bur oak | *Q. macrocarpa* |
| Shagbark hickory | *Carya ovata* |
| American basswood | *Tilia americana* |
| Black cherry | *Prunus serotina* |
| Elm | *Ulmus* species |
| Othern eastern hardwoods: | |
| Butternut | *Juglans cinerea* |
| Eastern hophornbeam (ironwood) | *Ostrya virginiana* |
| American hornbeam (blue-beech) | *Carpinus caroliniana* |

Table 7.—*Area of commercial forest land, by area condition and ownership classes, Maine, 1971*

[In thousands of acres]

| Area-condition class[1] | All ownerships | National Forest | Other public | Forest industry | Farmer and other |
|---|---|---|---|---|---|
| Class *10-40* | 39.6 | — | 0.2 | 11.7 | 27.7 |
| Class *50* | 7,319.8 | 11.3 | 131.1 | 3,701.1 | 3,476.3 |
| Class *60* | 7,823.2 | 20.6 | 107.8 | 3,904.4 | 3,790.4 |
| Class *70* | 1,711.7 | 5.6 | 34.9 | 637.8 | 1,033.4 |
| All classes | 16,894.3 | 37.5 | 274.0 | 8,255.0 | 8,327.8 |

[1]Class *10*.—Areas fully stocked with desirable trees and not overstocked.
Class *20*.—Areas fully stocked with desirable trees, but overstocked with all live trees.
Class *30*.—Areas medium to fully stocked with desirable trees, and with less than 30 percent of the area controlled by other trees and/or inhibiting vegetation or surface conditions that will prevent occupancy by desirable trees.
Class *40*.—Areas medium to fully stocked with desirable trees and with 30 percent or more of the area controlled by other trees and/or conditions that ordinarily prevent occupancy by desirable trees.
Class *50*.—Areas poorly stocked with desirable trees, but fully stocked with growing-stock trees.
Class *60*.—Areas poorly stocked with desirable trees, but with medium to full stocking of growing-stock trees.
Class *70*.—Areas poorly stocked with desirable trees, and poorly stocked with growing-stock trees.

Table 8.—*Area of commercial forest land, by potential site productivity and ownership classes, Maine, 1971*

[In thousands of acres]

| Growth-per-acre class (cubic feet) | All ownerships | National Forest | Other public | Forest industry | Farmer and other |
|---|---|---|---|---|---|
| 120 to 165 | 2,386.3 | 4.9 | 38.7 | 1,136.4 | 1,206.3 |
| 85 to 120 | 5,165.8 | 7.3 | 48.6 | 2,852.8 | 2,257.1 |
| 50 to 85 | 5,854.3 | 13.6 | 104.8 | 2,839.3 | 2,896.6 |
| Less than 50 | 3,487.9 | 11.7 | 81.9 | 1,426.5 | 1,967.8 |

[1]International ¼-inch rule.
[2]Includes 104.4 million board feet of red pine.
[3]Includes 107.5 million board feet of black spruce.
[4]Includes 16.7 million board feet of select white oaks and 7.2 of other red oaks.
[5]Includes 198.2 million board feet of black ash.
[6]Includes 208.5 million board feet of basswood, 276.2 of elm, and 91.4 of other hardwood species.

Table 19.—*Net volume of sawtimber on commercial forest land, by species and quality classes, Maine, 1971*

[In millions of board feet][1]

| Species | All classes | Standard-lumber logs | | | |
|---|---|---|---|---|---|
| | | Grade 1 | Grade 2 | Grade 3 | Grade 4[2] |
| Softwoods: | | | | | |
| White pine[3] | 4,568.3 | 162.5 | 406.9 | 2,276.3 | 1,722.6 |
| Other softwoods[4] | 18,887.6 | — | — | — | — |
| Total softwoods | 23,455.9 | 162.5 | 406.9 | 2,276.3 | 1,722.6 |
| Hardwoods: | | | | | |
| Northern red oak | 693.5 | 122.8 | 161.0 | 344.5 | 65.2 |
| Yellow birch | 1,608.1 | 205.3 | 418.7 | 848.0 | 136.1 |
| Paper birch | 646.9 | 50.5 | 145.5 | 397.8 | 53.1 |
| Sugar maple | 3,234.6 | 565.8 | 816.8 | 1,487.5 | 364.5 |
| Soft maples | 2,123.6 | 152.4 | 430.5 | 1,222.4 | 318.3 |
| Beech | 998.8 | 18.2 | 77.4 | 705.8 | 197.4 |
| White ash | 491.6 | 89.6 | 128.5 | 198.9 | 74.6 |
| Aspen | 690.6 | 33.6 | 112.8 | 391.1 | 153.1 |
| Other hardwoods | 576.1 | 99.1 | 151.6 | 270.6 | 54.8 |
| Total hardwoods | 11,063.8 | 1,337.3 | 2,442.8 | 5,866.6 | 1,417.1 |
| Hardwood quality (in percent) | 100 | 12 | 22 | 53 | 13 |

[1]International ¼-inch rule.
[2]Grade 4 applies only to the pines. For hardwoods the volumes in this column are construction logs.
[3]Includes 104.4 million board feet of red pine.
[4]Species other than pines were not graded into standard-lumber logs.

Table 20.—*Annual net growth and removals of growing stock and sawtimber on commercial forest land, by species, Maine, 1970*

| Species | Growing stock | | Sawtimber | |

[1]International ¼-inch rule.
[2]Rough-wood basis, includes chips converted to equivalent standard cords.
[3]Includes railroad ties, shingle bolts, and fence rails; does not include residues used for agricultural bedding.
[4]No mine timbers are produced in Maine.

| Inventory | 6,490.2 | 6,716.9 | 6,858.4 | 6,913.6 |
| Total | | | | |
| Cut | 408.7 | 568.1 | 725.1 | 858.1 |
| Growth | 710.8 | 771.2 | 828.9 | 862.4 |
| Inventory | 21,253.4 | 23,727.9 | 25,212.8 | 25,703.9 |
| | | SAWTIMBER | | |
| | | *Million board feet*[2] | | |
| Softwoods: | | | | |
| Cut | 878 | 833 | 1,063 | 1,242 |
| Growth | 1,224 | 1,060 | 1,151 | 1,180 |
| Inventory | 23,456 | 26,369 | 27,877 | 27,940 |
| Hardwoods: | | | | |
| Cut | 421 | 286 | 299 | 302 |
| Growth | 398 | 269 | 270 | 265 |
| Inventory | 11,064 | 10,959 | 10,717 | 10,379 |
| Total: | | | | |
| Cut | 1,299 | 1,119 | 1,362 | 1,544 |
| Growth | 1,622 | 1,329 | 1,421 | 1,445 |
| Inventory | 34,520 | 37,328 | 38,594 | 38,319 |

[1]Based upon the following assumptions: Farmland abandonment and reversion to forest will be offset by forest land lost by land clearing, growth rates will continue to be the same for the next 30 years, and trends in forestry programs will continue at the same rate as in the past. Timber available for cutting in this projection is assumed to be that amount that will bring growth and cut into balance by the end of 30 years.

[2]International ¼-inch rule.

Table 32.—*Land area of Maine, by land classes and geographic units, 1971*

| Geographic unit | Total land area | Nonforest land area | Forest-land area | | | | |

[1]Includes 410 thousand red pine trees.
[2]Includes 99 thousand black spruce trees.
[3]Includes 815 thousand white oak trees.
[4]Includes 91 thousand black ash trees.
[5]Includes 439 thousand basswood trees, 450 elm, and 597 black cherry.

Table 58.—*Growing-stock volume in the AROOSTOOK COUNTY UNIT, by species and diameter classes, 1971*

[In millions of cubic feet]

| Species | Total | Diameter class (inches at breast height) | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | 5.0-6.9 | 7.0-8.9 | 9.0-10.9 | 11.0-12.9 | 13.0-14.9 | 15.0-16.9 | 17.0-18.9 | 19.0-20.9 | 21.0-28.9 | 29.0+ |
| White pine | 53.2 | 2.8 | 4.3 | 2.1 | 3.4 | 7.1 | 4.0 | 9.0 | 4.6 | 14.5 | 1.4 |
| White spruce[1] | 320.9 | 91.5 | 93.4 | 63.5 | 32.8 | 15.1 | 12.4 | 9.9 | 1.1 | 1.2 | — |
| Red spruce | 1,255.2 | 270.4 | 270.4 | 228.3 | 182.1 | 135.0 | 82.6 | 47.4 | 22.3 | 16.7 | — |
| Balsam fir | 1,844.1 | 650.9 | 595.6 | 363.0 | 155.4 | 56.7 | 16.1 | 4.6 | 1.8 | — | — |
| Hemlock | 84.2 | 10.9 | 10.2 | 12.4 | 12.3 | 11.4 | 4.5 | 7.7 | 4.9 | 9.9 | — |
| No. white-cedar | 382.2 | 86.2 | 89.9 | 84.6 | 58.8 | 29.2 | 22.1 | 8.2 | .6 | 2.6 | — |
| Other softwoods | 32.5 | .4 | 6.8 | 8.1 | 11.8 | 4.0 | 1.4 | — | — | — | — |
| Total softwoods | 3,972.3 | 1,113.1 | 1,070.6 | 762.0 | 456.6 | 258.5 | 143.1 | 86.8 | 35.3 | 44.9 | 1.4 |
| Yellow birch | 129.5 | 16.1 | 27.5 | 20.2 | 20.6 | 17.1 | 10.6 | 5.8 | 7.0 | 4.6 | — |
| Paper birch | 91.1 | 42.2 | 10.7 | 17.2 | 10.5 | 5.3 | 2.1 | 1.5 | — | 1.6 | — |
| Sugar maple | 337.1 | 42.7 | 33.6 | 49.4 | 32.9 | 41.6 | 49.8 | 20.6 | 27.4 | 38.4 | .7 |
| Soft maples | 213.9 | 37.4 | 40.7 | 31.4 | 34.6 | 31.5 | 24.0 | 5.9 | 5.0 | 3.4 | — |
| Beech | 180.1 | 16.5 | 30.7 | 31.8 | 45.5 | 30.3 | 12.8 | 11.2 | .7 | .6 | — |
| White ash[2] | 66.0 | 10.7 | 13.8 | 10.2 | 15.4 | 7.2 | 6.7 | .9 | 1.1 | — | — |
| Aspen | 231.7 | 42.9 | 44.3 | 57.4 | 44.9 | 24.5 | 10.8 | 6.2 | .7 | — | — |
| Other hardwoods[3] | 37.3 | 5.8 | 5.8 | 6.4 | 8.6 | 5.2 | 2.8 | 1.7 | 1.0 | — | — |
| Total hardwoods | 1,286.7 | 214.3 | 207.1 | 224.0 | 213.0 | 162.7 | 119.6 | 53.8 | 42.9 | 48.6 | .7 |
| All species | 5,259.0 | 1,327.4 | 1,277.7 | 986.0 | 669.6 | 421.2 | 262.7 | 140.6 | 78.2 | 93.5 | 2.1 |

[1]Includes 43.7 million cubic feet of black spruce.
[2]Includes 35.0 million cubic feet of black ash.
[3]Includes 22.1 million cubic feet of balsam poplar, 2.5 of basswood, 1.5 of black cherry and 11.2 of elm.

Table 59.—*Growing-stock volume in the CAPITOL REGION UNIT, by species and diameter classes, 1971*

[In millions of cubic feet]

| Species | Total | Diameter class (inches at breast height) | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | 5.0-6.9 | 7.0-8.9 | 9.0-10.9 | 11.0-12.9 | 13.0-14.9 | 15.0-16.9 | 17.0-18.9 | 19.0-20.9 | 21.0-28.9 | 29.0+ |
| White pine[1] | 188.6 | 32.5 | 27.9 | 28.2 | 20.4 | 22.1 | 16.5 | 6.0 | 13.3 | 16.3 | 5.4 |

| Total hardwoods | 1,649.9 | — | 500.0 | 414.4 | 242.3 | 225.2 | 109.3 | 151.3 | 7.4 |
| All species | 3,629.5 | 750.3 | 962.0 | 699.4 | 456.9 | 315.2 | 170.0 | 253.2 | 22.5 |

[1]Includes 23.3 million board feet of red pine .
[2]Includes 3.2 million board feet of white oaks.
[3]Includes 7.4 million board feet of black ash.
[4]Includes 23.3 million board feet of basswood, 7.6 of black cherry, and 4.7 of elm.
Note: For county breakdowns of species in this unit, see table 105.

Table 76.—*Volume of sawtimber in the AROOSTOOK COUNTY UNIT, by species and log-quality classes, 1971*

[In millions of board feet][1]

| Species | All classes | Standard-lumber logs | | | |
|---|---|---|---|---|---|
| | | Grade 1 | Grade 2 | Grade 3 | Grade 4[2] |
| White pine | 188.8 | 29.2 | 40.2 | 78.6 | 40.8 |
| Other softwoods[3] | 6,195.8 | — | — | — | — |
| Total softwoods | 6,384.6 | 29.2 | 40.2 | 78.6 | 40.8 |
| Yellow birch | 257.0 | 21.4 | 67.0 | 146.3 | 22.3 |
| Paper birch | 79.0 | 7.5 | 17.0 | 47.9 | 6.6 |
| Sugar maple | 856.0 | 115.7 | 218.2 | 411.5 | 110.6 |
| Soft maples | 396.7 | 43.4 | 104.1 | 185.4 | 63.8 |
| Beech | 373.4 | 2.6 | 40.0 | 284.1 | 46.7 |
| White ash | 118.3 | 20.8 | 30.8 | 41.4 | 25.3 |
| Aspen | 322.9 | 8.5 | 59.1 | 184.4 | 70.9 |
| Other hardwoods | 72.7 | 13.0 | 7.8 | 34.1 | 17.8 |
| Total hardwoods | 2,476.0 | 232.9 | 544.0 | 1,335.1 | 364.0 |

[1]International ¼-inch rule.
[2]Grade 4 applies only to the pines. For hardwoods the volumes in this column are for construction logs.
[3]Species other than pines were not graded into standard-lumber logs.

Table 77.—*Volume of sawtimber in the CAPITOL REGION UNIT, by species and log-quality classes, 1971*

[In millions of board feet][1]

| Species | All classes | Standard-lumber logs | | | |
|---|---|---|---|---|---|
| | | Grade 1 | Grade 2 | Grade 3 | Grade 4[2] |
| White pine[3] | 597.0 | 1.9 | 36.9 | 250.1 | 308.1 |

MAPLE–BEECH–BIRCH
ASPEN–BIRCH
NONFOREST

THE FOREST SERVICE of the U. S. Department of Agriculture is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives — as directed by Congress — to provide increasingly greater service to a growing Nation.
